## **The Archaeology of the Mantle Site (AlGt-334)**

### **A Report on the Stage 3-4 Salvage Excavation of the Mantle Site (AlGt-334) Part of Lot 33, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario**

#### **EXECUTIVE SUMMARY**

Archaeological Services Inc. was contracted by Lebovic Enterprises of Stouffville, Ontario to conduct a Stage 3-4 excavation of the Mantle site (AlGt-334), located within part of Lot 33, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario.

The Stage 3 excavations were conducted in 2003-2004, and involved the pedestrian survey of the Lebovic Enterprises lands, the controlled surface collections of the artifacts encountered and the excavation and hand-screening of 58 one metre square plough zone test units in addition to a series of one metre square test units excavated within the three middens. This work was conducted under the project direction of Mr. Martin Cooper and Dr. Ronald Williamson, and under the field direction of Mr. Andrew Clish (2003-2005).

The Stage 4 excavation was conducted under the project management of Dr. Ronald Williamson and the field direction of Mr. Andrew Clish in 2004 and 2005. The Stage 4 archaeological mitigation of the Mantle site (AlGt-334) involved the removal of approximately 4.5 hectares of topsoil by mechanical means revealing a settlement pattern consisting of 98 longhouses and five discrete exterior activity areas including an east-central “plaza” area that appears to have been used in the early phase of the site. At least three distinct multi-row palisades were encountered, with a trench midden running parallel to the palisade. One midden and two midden-like concentrations were identified and hand-excavated in one metre square units to sterile subsoil. A total of 1,415 subsurface cultural features was recorded, both within and exterior to the house structures. A total of 104,432 precontact artifacts were recovered from the 2003-2005 Stage 3-4 salvage excavation of the site, consisting of ceramics, flaked lithic and ground stone, metal artifacts and floral and faunal remains. The analysis of the archaeological data suggests that the Mantle site is an early sixteenth century ancestral Wendat village (A.D. 1500-1530) that ranged between 2.0 and 3.0 hectares in size.

The Stage 3-4 mitigative excavation of the Mantle site also exposed remnants of the Euro-Canadian occupation of the property. These remnants could be separated into two components. The first, a post-1870 component, consisted of a few re-deposited artifacts from the demolition of the late nineteenth-century farmhouse, a number of miscellaneous features, and five animal burials around a pair of late nineteenth/early twentieth-century barns. The second component consisted of a variety of early-to-mid nineteenth-century artifacts recovered from the block excavated Midden 1 area. This area is in close proximity with a former mill complex that stood on the property between circa 1851 and 1911 and the location of a mid-nineteenth-century farmhouse. A total of 6,612 Euro-Canadian artifacts were recovered from Midden 1, midden-like concentration #2 and #3 and from the 25 Euro-Canadian features documented on the Mantle site (AlGt-334).

## PROJECT PERSONNEL

<i>Project Directors:</i>	Dr. Ronald F. Williamson, PhD Managing Partner & Chief Archaeologist Mr. Martin S. Cooper, MA Senior Archaeologist & Partner	
<i>Field Directors:</i>	Mr. Andrew Clish, BES Senior Archaeologist for the Planning Applications and Special Projects Division	
<i>Field Archaeologists (permanent):</i>	<b>2003:</b> Dr. Jennifer Birch, PhD, University of Georgia Ms. Aleksandra Pradzynski, Hons BSc Staff Archaeologist for Planning Applications and Special Projects Division Ms. Annie Veilleux, Hon. BA, MA Staff Archaeologist and Cultural Heritage Specialist BHCHLP Division  <b>2004:</b> Ms. Annie Veilleux (Assistant Field Director)    Mr. James Herbert Ms. Eda Ataergin    Ms. Andrea Jackson Ms. Karen Blackburn    Ms. Biljana Jovanovic Mr. Nick Charalambu    Ms. Charlene Murphy Ms. Stephanie Folgado  <b>2005:</b> Ms. Aleksandra Pradzynski (Assistant Field Director) Ms. Eda Ataergin Mr. James Herbert Ms. Andrea Jackson	
<i>Additional Field Archaeologists (rotational):</i>	Ms. Amy Au Ms. Zeeshan Abedin Ms. Kristi Bates Ms. James Caldwell Ms. Andrea Carnevale Mr. Peter Carruthers Ms. Katherine Cappella Mr. Neil Chisholm Mr. Marin Cooper Ms. Kristine Crawford Staff Archaeologist and Manager of Laboratory Services Ms. Meredith Czaniecki Ms. Diane Ferreira Ms. Jennie Fiddes Ms. Vanessa Forrest Ms. Bev Garner	Ms. Rebecca George Dr. Katie Hull Ms. Wai Kok Ms. Denise McGuire Ms. Eva MacDonald Dr. Stephen Monckton Mr. Wesley Oldham Ms. Caitlin Pearce Mr. Matthew Pearce Ms. Eva MacDonald Mr. Mark Pane Mr. Dave Robertson Mr. Norbert Stanchly Mr. Doug Todd Mr. Brian Williams Ms. Robin Walton
<i>Report Preparation:</i>	Dr. Jennifer Birch Ms. Andrea Carnevale Mr. Andrew Clish	Dr. Suzanne Needs-Howarth Ms. Deborah A. Steiss Ms. Aleksandra Pradzynski

	Mr. Martin Cooper Dr. Crystal Forrest Dr. Stephen Monckton	Mr. Anatolijs Venovcevs Dr. Ron Williamson Mr. Robert Wojtowicz

Gradall Operators:	Mr. Jack Rooney Mr. Gord Sloan	Mr. Mike Rooney
Report Compilation and Editing:	Ms. Andrea Carnevale Dr. Crystal Forrest	Mr. David Robertson Dr. Ronald F. Williamson

## ACKNOWLEDGEMENTS

Our sincerest appreciation is extended to the Huron-Wendat Nation and particularly to Heather Bastien and Luc Lainé for their support during our analyses of the site.

This report has been completed thanks to the dedication and collaborative efforts of an extensive team of archaeologists, analysts, researchers, and colleagues. Foremost among these is Andrew Clish, who directed the excavations of the site, produced the map of its settlement patterns and helped to unravel the occupational history of the village. With almost 30 years of experience excavating Iroquoian village sites, Andrew is unparalleled in Ontario for experience on the ground.

We are also indebted to many regular ASI crew members who participated in excavations at the site between 2002 and 2005: Eda Ataergin, Amy Au, Katherine Cappella, Andrea Carnevale, Peter Carruthers, Neil Chisholm, David Cooper, Meredith Czaniecki, Jennie Fiddes, Rebecca George, James Herbert, Andrea Jackson, Denise McGuire, Matthew Pearce, Wesley Oldham, Aleksandra Pradzynski, David Robertson, Debbie Steiss, Annie Veilleux, Brian Williams, Bruce Welsh and all of the other ASI personnel who assisted in these efforts. As an extension of our crew, Mike and Jack Rooney of Rooney Brothers Gradall provided expertise in mechanical soil removal and Joe Thompson and David Moir provided an opportunity for aerial photography during excavation.

Thanks to Margie Kennedy and the Toronto Region Conservation Authority (TRCA) for providing data on the Seed-Barker site.

We are particularly indebted to Andrea Carnevale, who assumed the responsibility for researching the iron object. With determination, Andrea tracked down the region of origin for the piece representing a significant contribution to northeastern North American archaeology. We would also like to acknowledge George Hoytena and his colleagues at Team Industrial in Oakville and Susan Stock and Heidi Sobol of the Conservation Department at the Royal Ontario Museum for their help with radiography and James Bradley, George Hammel, Jim Tuck and Peter Ramsden for their comments on the discovery of this early piece of iron.

Steve Monckton identified the palaeobotanical remains and the zooarchaeological analysis was conducted by Suzanne Needs-Howarth. Dr. Needs-Howarth would in turn, like to thank Dr. T. Max Friesen of the Department of Anthropology at the University of Toronto for allowing access to the Howard G. Savage Faunal Archaeo-Osteology Collection; Kevin Seymour of the Royal Ontario Museum, Vertebrate Paleontology, for providing access to recent salmonid vertebrae; Erling Holm of the Royal Ontario Museum, Ichthyology, for tracing records of Atlantic salmon in Duffins Creek; Don Stacey and Maureen Zubowski of the Royal Ontario Museum, Invertebrate Palaeontology, for confirming the crayfish identification and Nelson Amaral of the Toronto Region Conservation Authority for facilitating access to fish data for their watersheds.

Drs. Linda Howie and Alexis Dolphin conducted the petrographic analysis of ceramics from the site and Ms. Brandi Lee MacDonald and Dr. Ron Hancock undertook the identification of the origin of the copper beads from Mantle using the facilities of MNR at McMaster University.

We are also grateful to Greg Braun, Peter Carruthers, Marty Cooper, Gord Dibb, Bill Engelbrecht, William Fox, Martha Latta, Rob MacDonald, Kostalena Michelaki, Robert Pearce, Rob Pihl, David Robertson, Debbie Steiss, Andrew Stewart, and Tony Wonderley for thoughtful discussions regarding various aspects of the Mantle research.

The production of this report was aided immeasurably by John Howarth, who photographed the artifacts, Andrea Carnevale, who helped produce the figures and photographs, and Jonas Fernandez who assisted with GIS-based analyses and mapping. Shady Abbas and Sarina Finlay were also of assistance in this regard.

Thanks to Jean-Luc Pilon and Stacey Girling-Christie at the Canadian Museum of Civilization for facilitating access to the collections from the Pugh, Best and Spang sites; Justin Jennings, April Hawkins, and Adrienne Desjardine of the Royal Ontario Museum for access to collections from the Aurora site; Kathy David for access to additional collections and reports on file at the University of Toronto; Dorie Billich and Krista Rauchenstein of the Whitchurch-Stouffville Museum for access to collections from sites in the Holland River drainage and Gord Dibb provided access to his collections from the four sites north of Mantle, to which the community relocated.

Andrea Carnevale would also like to thank Jennifer Birch and Ron Williamson, the latter of whom enabled her to play a role in telling the story of the Mantle site, for their faith and confidence, and especially for charging her with the task of researching the “lump of rust.” She would also like to express her sincerest appreciation and thanks to Michael Barkham, Lloyd Johnston, George Hoytena, Jim Bradley, and Kathy Ehrhardt for their immense support and encouragement during her metal research. Thank you to Susan Stock and Heidi Sobol for their helpful comments and support during the second round of X-rays. Thank you to Brandi Lee MacDonald, Linda Howie, Eva MacDonald, and David Robertson for being incredible teachers and always willing to talk science applications and artifacts. Finally, a special thank you to Robin Bicknell, Alex McIntosh, Robin Waite, Matt Phillips, Robert Beal, Harrison Freedman, Jordan Jackson, and Elliott Halpern of Yap films for their excitement and encouragement and allowing this archaeologist to follow her research to Basque Country.

The excavation of the site was funded by Lebovic Enterprises and portions of the analyses presented in this report were supported by a Canada Graduate Doctoral Scholarship and a Postdoctoral Fellowship from the Social Sciences and Humanities Research Council of Canada for Jennifer Birch. Part of the story of Mantle is told in an award-winning film, involving Ron, Jennifer, and Andrea, which can be seen on the Canadian History Channel. It is entitled *Curse of the Axe*.

## 1.0 INTRODUCTION: THE EXCAVATION OF THE MANTLE SITE

*Andrea Carnevale and David Robertson*

Archaeological Services Inc. was contracted by Lebovic Enterprises to carry out further Stage 3 assessment and Stage 4 salvage excavation of those portions of the Mantle site (AIGt-334) located on the east half of Lot 33, Concession 9 in the former Township of Markham, now the Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario (Figure 1). This work was a continuation of a larger project involving the Stage 1-4 archaeological resource assessments within the Lebovic-Stouffville Development lands, which comprised parts of Lots 32, 33, and 34, Concession 9 (ASI 2004).

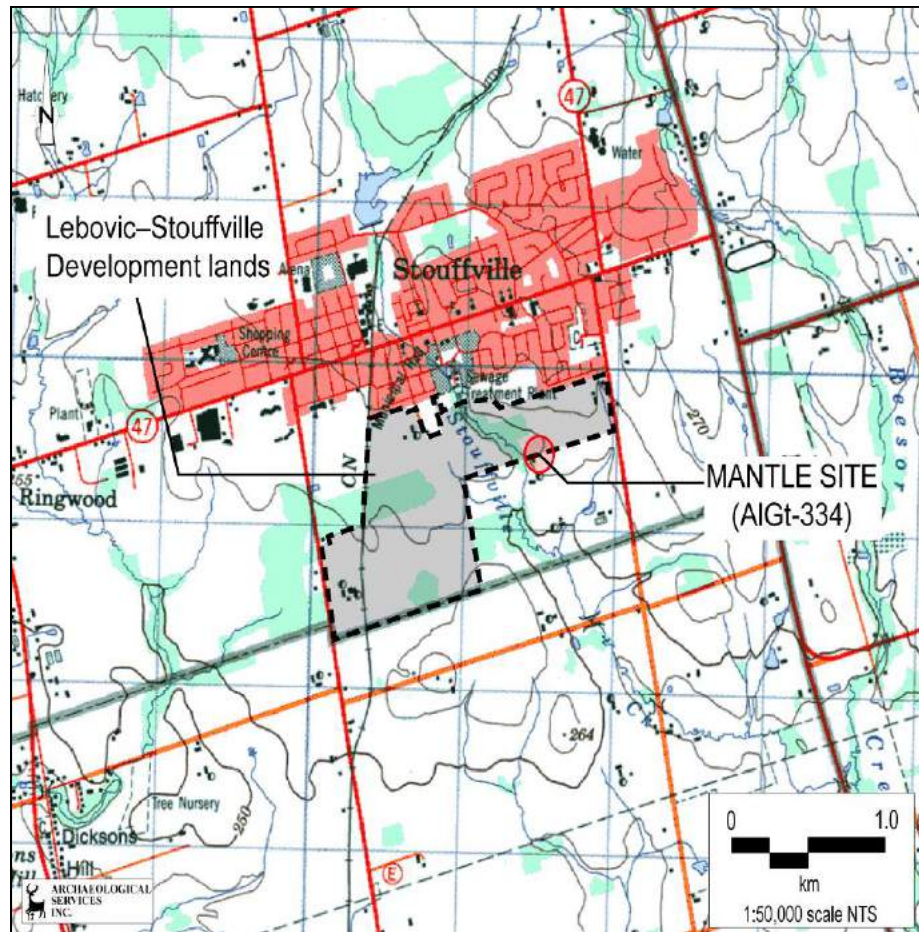

Figure 1: The location of the Mantle site (AIGt-334)  
(NTS Sheet 30 M/14 [Markham], ed. 9, 1994)

The Mantle site, registered with the OASD as AIGt-334, was a plough-disturbed ancestral Huron-Wendat village that occupied a broad promontory on the east side of Stouffville Creek, encompassing an area of approximately three hectares. The site dates to the early sixteenth century.

The Stage 3-4 fieldwork continued in late summer of 2003 through to mid-autumn of 2005 and was conducted under the project management of Mr. Martin Cooper (Stage 3) and Dr. Ronald Williamson (Stage 4). Mr. Andrew Clish served as the primary field director for the project, with additional direction provided by Dr. Bruce Welsh on limited occasions. This work was conducted in accordance with the Ontario Heritage Act (R.S.O. 1990) under archaeological license P046 issued to Mr. Clish.

Permission to access the study area and undertake all activities required to complete this project was given to Archaeological Services Inc. by Lebovic Enterprises.

This document constitutes a report of the completed Stage 3 and Stage 4 investigations of the Mantle site. The report is divided into ten major sections. The first reviews the environmental setting of the site, previous investigations conducted on the site, and the methods and techniques employed in this investigation. The following eight sections present a detailed description of the site settlement patterns, material culture, and evidence of subsistence strategies used by the site's occupants. The final section provides a brief summary and interpretations of the data presented.

It should also be noted that the site was the subject of a 2010 PhD Dissertation at McMaster University by Jennifer Birch entitled *Coalescent Communities in Iroquoian Ontario* and a volume about the site has been authored by Jennifer Birch and Ron Williamson and published by AltaMira Press, 2013. The volume is entitled *The Mantle Site: An Archaeological History of an Ancestral Wendat Community* and readers are referred to that volume for a more thorough review of the site in the context of Iroquoian archaeology in the lower Great Lakes Region.

## **1.1 Physiographic Setting**

The Mantle site is located within the South Slope physiographic region (Chapman and Putnam 1984), which forms the south slope of the Oak Ridges moraine. The region is characterized by gently to moderately rolling till plains cut through by steep stream valleys. The surface topography of the portion of the south slope in which the site is located is drumlinized, although the drumlins are widely scattered. While the soils are comprised of a variety of materials well suited for agricultural purposes, generally, soil in this region developed on sandier till in the east and predominantly clayey till in the west, however, localized variations are apparent throughout the region. The general surface characteristics of the site environs consist of gently rolling agricultural land. Stouffville Creek, a tributary of Duffins Creek, which is entrenched within a steep-sided valley, bisects the property and the Mantle site sits immediately to its west. Several smaller tributary or seasonal creeks and a series of wetlands also drain portions of the site environs.

## **1.2 Previous Investigations**

The assessment of the Lebovic–Stouffville Development lands commenced in 2003 under the project direction of Mr. Martin Cooper and Dr. Ronald Williamson, and entailed a Stage 1 and 2 assessment of the entire area and preliminary Stage 3 fieldwork of the Mantle site in June through November of 2003. This work was conducted and reported on under the professional archaeological licence (P047 and CIF# P047-012) issued to Dr. Bruce Welsh in accordance with the Ontario Heritage Act (1990) (ASI 2004a and b). The original documentation of the site and an account of ASI's preliminary investigations are provided in three of ASI's previous reports: *Stage 1 and 2 Archaeological Assessment of the Lebovic–Stouffville Development, Part of Lots 32, 33, and 34, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario*; *Investigation of the Mantle Site (AlGt-334) Part of Lot 33, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario*; and *Preliminary Report and*

*Stage 1-3 Archaeological Assessment of the Mantle site (AlGt-334), Part of Lot 33, Concession 9 (Formerly Township of Markham), Town of Whitchurch-Stouffville, Regional Municipality of York Ontario*, all of which were submitted to the Ministry of Tourism, Culture and Sport in January and June of 2004 and revised in February 2006.

The original Stage 1 research was conducted in order to identify any archaeological sites within the Lebovic–Stouffville Development lands subject property, prior to field examination and to assess the property’s archaeological potential based on its physiographic setting. It was concluded that the physiographic setting, history of nineteenth century land use, and nearby previously registered archaeological sites together pointed to significant archaeological potential for the property.

During the course of the Stage 2 survey, three precontact isolated finds, and two precontact sites – in addition to the Mantle site (AlGt-334) were encountered (ASI 2004a). Located on the east side of Stouffville Creek on the west half of Lots 32 and 33, Concession 9, the Mantle site occupied a broad promontory defined by the creek valley to the west, and by smaller swales to the north, east and south. During the course of the assessment, a mid-nineteenth century farm complex and milling operation was also found, in part, overlying the Mantle site. The buildings of the farm complex had been razed and large quantities of associated structural debris and earth had been bulldozed and stockpiled across the former complex. This former farm complex and milling operation corresponds to that indicated on the 1860 Tremaine map, which was occupied by James Bugg, a tenant of Samuel Boyer. The farm, grist and saw mill were inventoried during the Cultural Heritage Analysis carried out for the *Town of Whitchurch-Stouffville Functional Servicing Study, Stouffville Secondary Plan Area (East)* completed by ASI (2000). The north-western portion of the Mantle site had been extensively disturbed by the farm complex and the saw and grist mill, situated in the valley lands immediately below the farmhouse, may also have impacted hillside deposits. During the subsequent Stage 4 block excavation of Midden 1, a small segment of foundation of one of the associated mill building walls was encountered (Plate 1). Several artifacts were found in the midden deposit and have been included in the Stage 3-4 artifact analysis below. A barn is known to have been located in the south-western portion of the site (ASI 2004a) and also was found later to have seriously impacted the western edge of the site.

The preliminary Stage 3 assessment involved a controlled surface collection of the ploughed areas at transect intervals of five metres across the general site area and was then re-examined at one to two metre intervals (ASI 2004b). The location of each of the surface finds was then mapped within the overall five metre grid recording system established for the site. Approximately 3,000 surface artifacts were collected from 2,432 stations within the eastern portion of the site that had been ploughed (Figure 2). The surface scatter covered an area of 2.5 hectares.

Four one metre square test units, referenced to the overall site grid, were excavated along the periphery of the most dense concentration of artifacts, as this area was to be impacted by the installation of the services and road (proposed Street B), as indicated on Figure 2 (ASI 2004b). This exercise resulted in the recovery of 58 artifacts. For the most part, artifact yields within the plough zone were low, with an average of 14.5 items per unit and a range of 8 to 23.

In order to assist the development proponents in maintaining their servicing schedule, a series of trenches was mechanically excavated along the proposed alignments of the roads within and adjacent to the eastern limits of the site area to determine the character and extent of subsurface features within this zone, and to thoroughly document and remove them in advance of further disturbances on this portion of the property (Figure 3). An area of approximately 6,300 m<sup>2</sup> was exposed in this manner (ASI 2004b). This work resulted in the documentation of two sets of palisades on the eastern part of the site, together with ancillary features, and numerous alignments of posts (Figure 3).

This controlled surface collection and limited salvage excavations completed at the site established that it represented an extremely large, heavily fortified, ancestral Wendat settlement and therefore represented a significant archaeological resource with considerable potential to shed further light on both the causes and effects of community amalgamation and concomitant changes in Iroquoian socio-political structure, as well as on aspects of the daily lives of this particular community within the Stouffville Creek drainage (ASI 2004b).

### **1.3 2003 Stage 3 Investigations**

Further Stage 3 and Stage 4 fieldwork continued in late 2003 through to mid-autumn of 2005 and was conducted under the project management of Dr. Ronald Williamson. Mr. Andrew Clish served as the primary field director for the project, with additional direction provided by Dr. Bruce Welsh on limited occasions. This work was conducted in accordance with the Ontario Heritage Act (R.S.O. 1990) under archaeological license P046 issued to Mr. Clish.

Further Stage 3 investigations began in late August of 2003. The agricultural field in which the site was located had been freshly ploughed and allowed to weather for the purposes of completing a controlled surface collection. The site area was pedestrian surveyed at five metre intervals and all artifacts found on the surface were flagged (Plates 1-2). Field conditions were excellent. A site datum was established and tied into existing landmarks and property lines, and the locations of the surface artifacts were recorded relative to the datum by transit and tape. Due to the high number of surface artifacts encountered, however, the total number of artifacts within a 10 m grid square was recorded instead of the location of each individual artifact (Figure 4). The surface collection yielded 20,568 artifacts, distributed with no distinct pattern over an area of approximately 27,600 square metres (Figure 4).

Plate 1: Stage 3 Controlled Surface collection

Plate 2: Stage 3 Controlled Surface collection

A recording grid, fixed on the 500-200 datum, was extended across the site area to facilitate the excavation of 58 one metre square plough zone test units in addition to a series of one metre square test units excavated in each midden area (Figure 4 and Plate 3). The test units revealed typical plough zone soils measuring between 8 and 50 cm in depth.

Plate 3: Stage 3 Test unit Excavation

All soils were screened through six millimetre wire mesh to facilitate artifact recovery, and profiles and floors were examined for the presence of undisturbed cultural strata and/or subsurface settlement patterns in the form of features or post moulds. During the Stage 2 investigation of the woodlot and the slope area leading to Stouffville Creek, three areas of significant artifact density were identified and designated Midden 1, Midden 2 and Midden 3. These middens were subject to block excavation by hand during the Stage 4 salvage excavations, although Middens 2 and 3 soils were later found to have been redeposited during the occupation and/or demolition of the farmhouse.

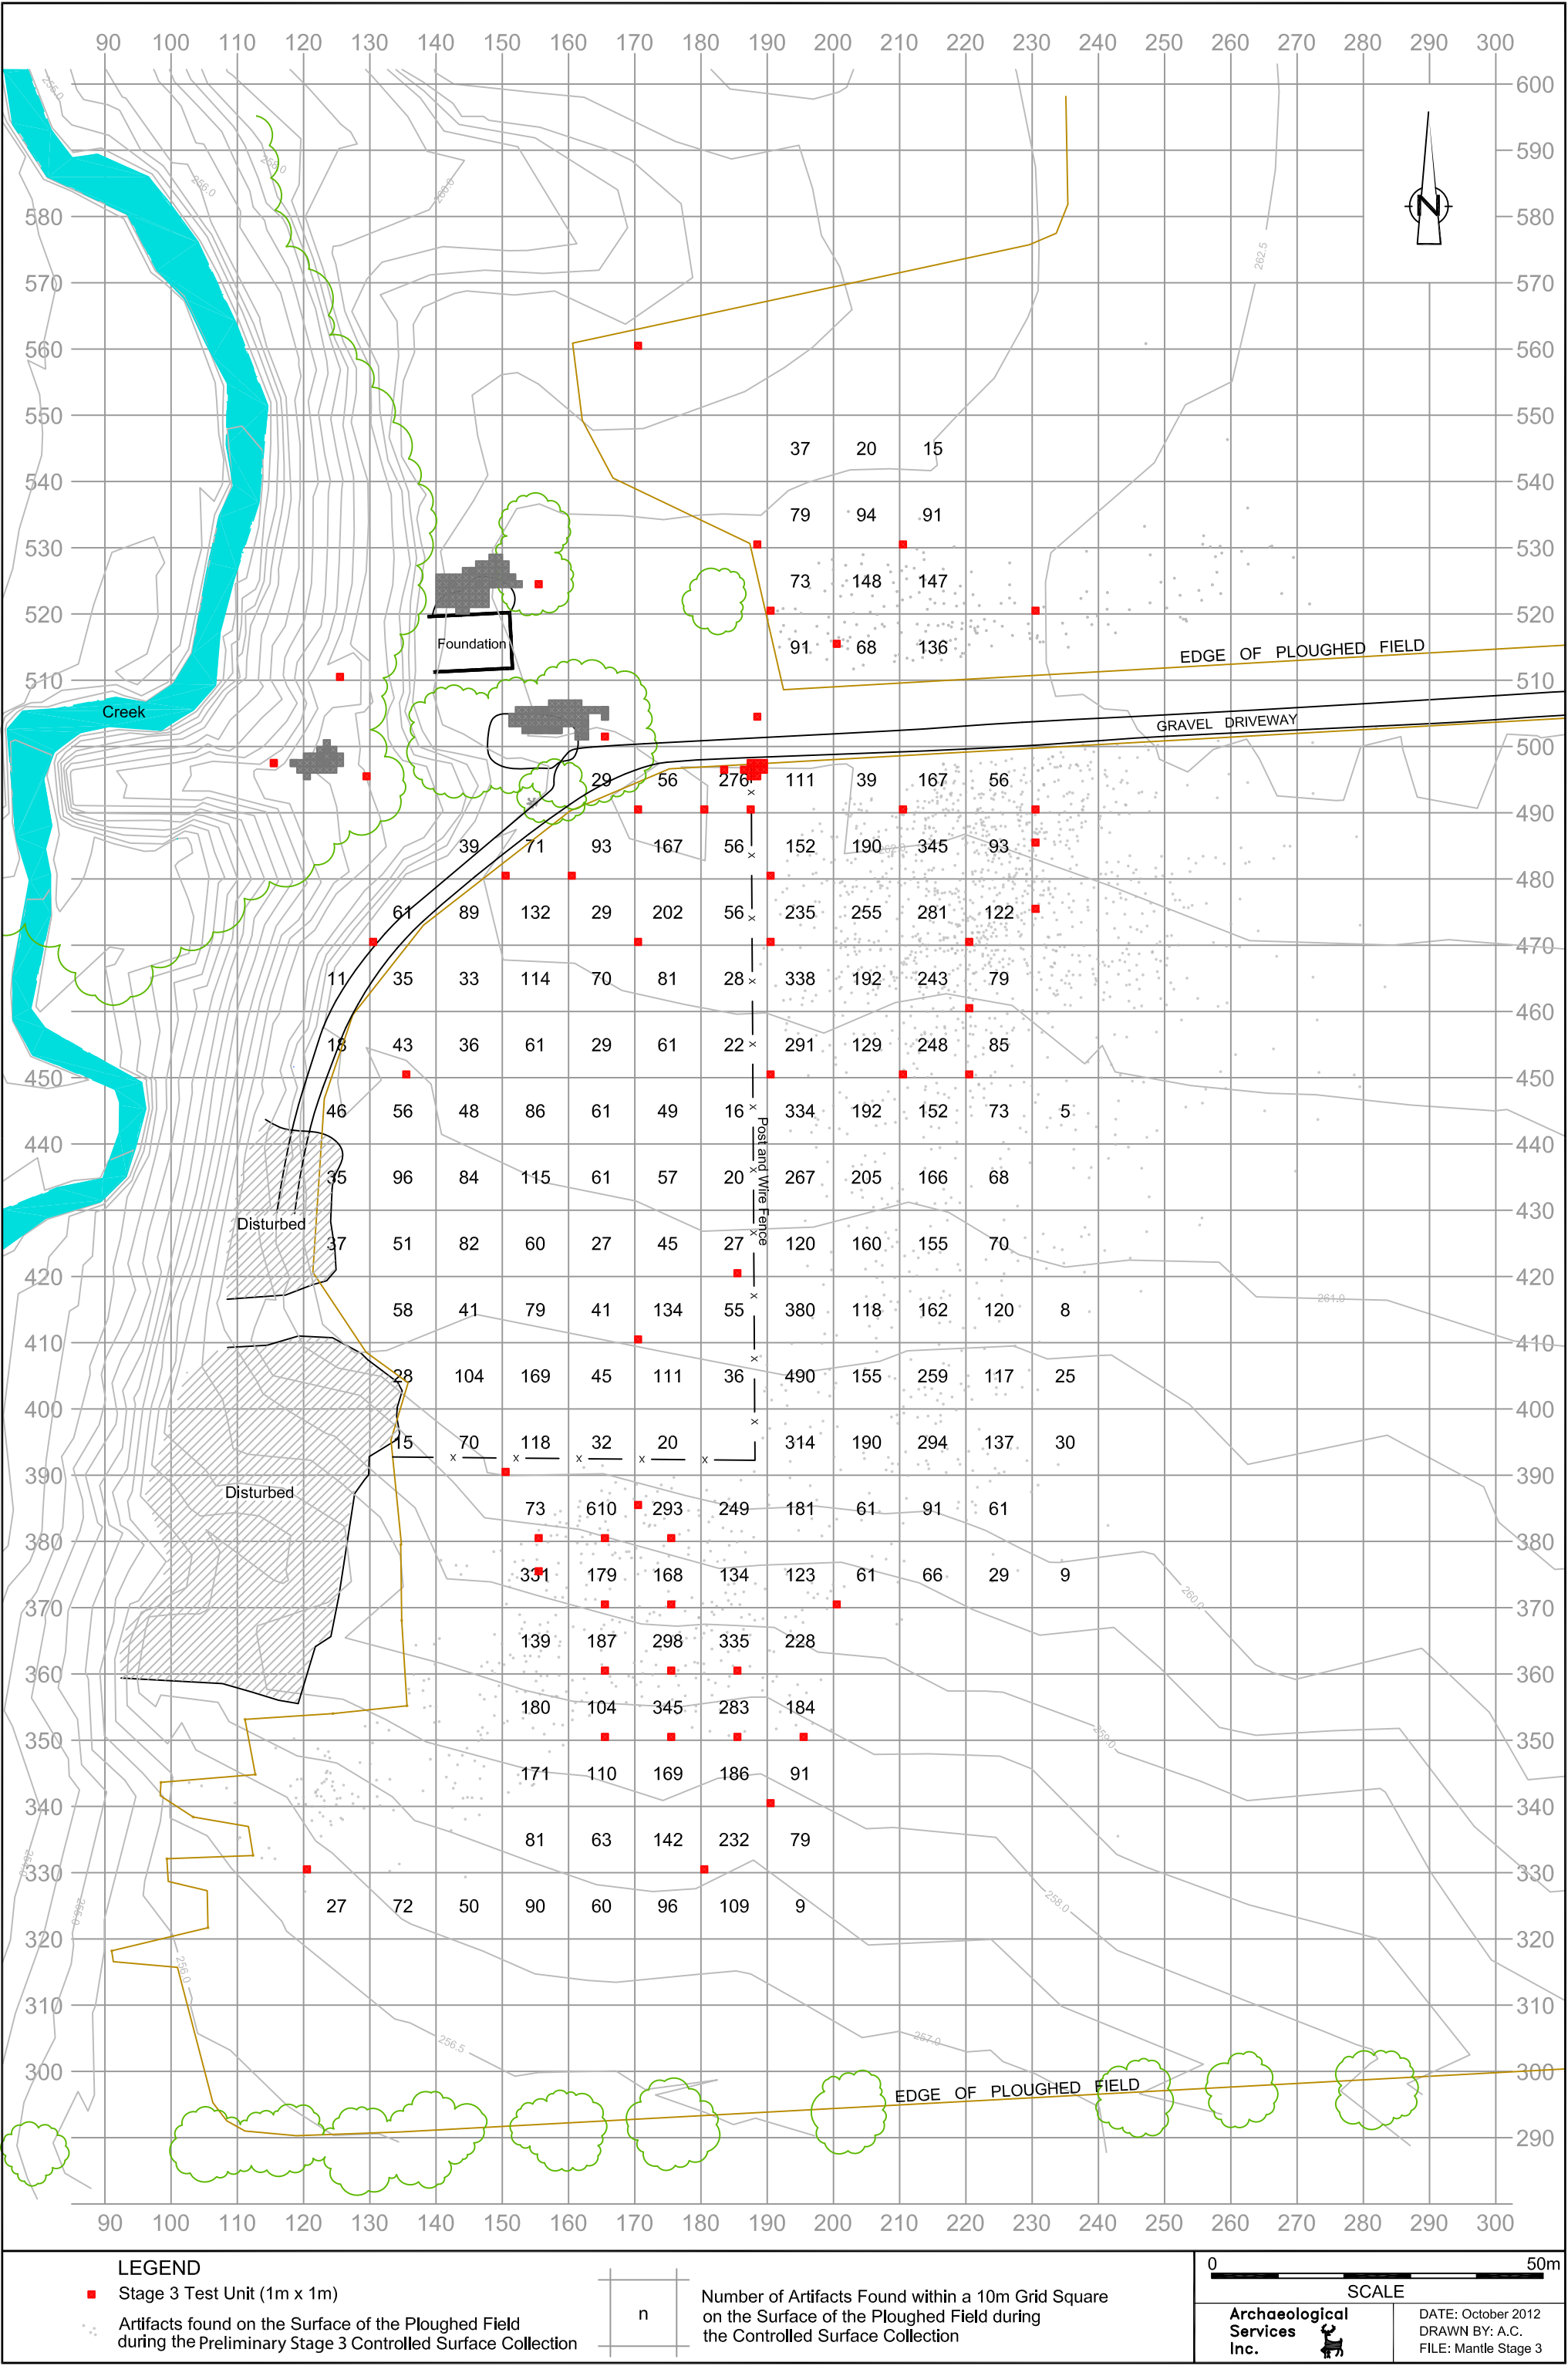

Figure 4: Results of the Stage 3 Controlled Surface Collection

## **1.4 Stage 4 Mitigation**

Upon the completion of the Stage 3 assessment, a Gradall equipped with a smooth bucket was employed to remove the plough zone from the site area (Plates 4-7), with the exception of the midden areas which were hand-excavated in one metre square units (Figure 5). All soils except those retained as flotation samples, were screened through six millimetre wire mesh.

The Stage 4 salvage excavation started in the spring of 2004, with the excavation of a series of trenches across the site area as estimated on the basis of the surface distribution of artifacts. Throughout the 2004 and 2005 field seasons, the excavation area was expanded as necessary to fully expose the settlement patterns within the occupation area of the settlement. In these operations, the plough zone, consisting of on average 30 centimetres of topsoil, was removed to reveal the subsoil and all potential features and post moulds were further examined through shovel-shining and troweling. As conditions warranted, and as the soil dried out during exposure to sun and wind, water was used to increase the visibility of the features. An area of approximately 4.5 hectares was exposed in this manner.

All settlement patterns were recorded by means of triangulation within the grid established on the site. Prior to triangulation, post moulds and features were further defined by troweling, and square plans were drawn. Features were recorded by triangulation to a centre point and feature plans and descriptions, contents, relationships, etc., were then recorded on pre-printed forms. Features were hand excavated, their fills being screened through six millimetre mesh, although the exact manner in which this was carried out depended upon their size and complexity. In all cases, they were sectioned along their central long axis, their profiles recorded and photographed, and the remaining fill removed and either screened or bagged for soil sample flotation. Larger or more complex features were sectioned and excavated in quadrants to provide the most useful vertical profiles for evaluating the nature of the feature. Profiles were both drawn and photographed for features, especially those with complex profiles.

The location and diameter of each post mould was recorded on pre-printed forms. They were sectioned when necessary to obtain a depth and orientation, and/or to distinguish between large support posts and small pits. Comments on fill and contents were recorded. Artifacts recovered during feature and post excavations were bagged according to provenience. Flotation samples were taken from features in a variety of contexts from across the site.

The plough zone removal resulted in the documentation of 98 house structures across the settlement area and a total of 1,415 features in association with the houses (Figure 5). One slope midden, two midden-like features associated with the slope midden, and a borrow trench midden were also documented. From the subsurface features, plough zone test units, and the excavation of the middens in one-metre square units, 96,405 ceramic artifacts, 6,369 flaked lithic artifacts, 488 ground stone artifacts, 1,166 worked bone artifacts and four metal artifacts were recovered. The flotation of 212 soil samples from various contexts across the site yielded a variety of floral remains.

During the Stage 4 salvage excavation, the slope to the west of the top of bank was test pitted. This work proceeded northward from the south end of the site to approximately the mill race landform, which was situated immediately south of the former farmhouse. This feature likely represents a groundworks feature associated with a mill pond dam or race associated with the heavily disturbed nineteenth-twentieth century component of the Mantle site. No additional precontact material was encountered during this work, nor were any intact deposits potentially associated with the mill complex identified. In addition, the valley floor down slope was also test pitted at five metre intervals, despite the fact that these lands were poorly drained and exhibited little to no archaeological potential. Nothing was found.

## **1.5 Cemetery Investigation**

On May 10<sup>th</sup>, 2006 human remains were discovered during construction activities to the southwest of the site in the valley lands located between the site and Stouffville Creek (Appendix A). The remains were discovered in a drainage ditch approximately 20 metres in length that had been excavated in late October of 2005 in order to alleviate drainage of the area of the proposed SWM pond. In the spring of 2006, the area to the west of this ditch was bulldozed in preparation for a service corridor. It was during this phase of construction activities that the remains were discovered in the bank and along the floor of the ditch.

The remains of at least three individuals were initially encountered. Upon their discovery, the police and coroner were called and the cemetery was quickly assessed and of no forensic interest. ASI was asked to conduct a cemetery investigation. These investigations were conducted under the project management of Dr. Ronald Williamson, under archaeological license (P046) issued to Mr. Andrew Clish in accordance with the Ontario Heritage Act (1990).

Work on the site was supervised by Mr. Andrew Clish and monitored by a designated representative of the Huron-Wendat First Nation who continued monitoring throughout various stages of the project. A total of 37 interments were found clustered in an area below the top of slope in the valley lands. Within these burials, 31 were adults, two adolescents, and five infants / juveniles were documented. It was suggested that together, these burials represented either a portion of the Mantle site primary cemetery where people were buried prior to them being moved at the end of the tenure of the village to the village ossuary, or a cemetery of those who were not intended for ossuary reburial (ASI 2011).

As the cemetery area was to be impacted by a service corridor, which had already been partially constructed on the opposite side of Stouffville Creek, the service corridor was rerouted to the north of the existing corridor, maintaining a distance of 10 metres from the closest burial in order to protect the cemetery from further disturbance.

## 2.0 SETTLEMENT PATTERNS

*Andrew Clish and Jennifer Birch*

### 2.1 Introduction

Excavation of the Mantle site resulted in the documentation of the following: ninety-eight longhouses; one slope midden (which was disturbed by the construction of the historic period mill buildings and farmhouse post-dating the village); two midden-like concentrations (which were found to be disturbed deposits from Midden 1); a multi-row perimeter palisade that was constructed in three separate phases; and a linear trench midden situated parallel to the late phase palisade (Figure 5).

Many of the longhouses located on the west side of the site had been disturbed or partially lost due to the construction of the historic farm and mill complexes and possible erosion and/or re-grading of the east slope of Stouffville Creek. Houses 11, 15, 40, 41, 44, 55, 56, 58, 62, 63, 80, 92, and 95 had been impacted by the construction of these complexes. The west ends of Houses 19, 20 and 37 were probably lost due to slope erosion or re-grading. House 35 was affected by both building construction and slope erosion. The two midden-like concentrations designated as Midden 2 and Midden 3 were almost certainly created as a result of the construction of the farm house foundations, with soil being dumped within the village precincts. Since very fragmentary material was recovered from Middens 2 and 3 on the north and south sides of the house foundation walls, it can be concluded this material was relocated by the excavation of the basement of the farmhouse and associated construction activities (Figure 5).

The settlement is composed of a palimpsest-like pattern of overlapping longhouses. This includes longhouse extensions, contractions and at least three distinct multi-row palisades. Of these palisades, two appear to be related to an “early” phase of village occupation (Figure 6), while the third palisade and the associated trench appear to be associated with a “late” or final phase of occupation (Figure 7). This suggests that there were several distinct construction events during the occupation of the site, as well as continual construction and rebuilding. In order to facilitate the interpretation of the chronological sequence of site development, the occupational history of the site has been divided into an early phase and late phase. The early phase includes longhouses that were contemporary with the initial outer perimeter palisade, while the late phase includes longhouses that existed at the same time as the terminal inner palisade and linear trench midden. The division of the occupation of the site into early and late phases is to some extent a heuristic device, as construction, demolition and relocation of structures would have been an on-going occurrence. Thus, some longhouses are assigned to both the early and late phases, which reflect the fact that they were inhabited mid-way through the total length of the occupation of the village.

The following section examines the above-mentioned settlement features, and provides both general observations and detailed descriptions. Metric attributes for each house are summarized in Table 1. A description of features with metric attributes is provided in Appendix B.

Figure 7: "Late" Phase of Village Occupation at the Mantle site (AlGt-334)

## 2.2 Village Plan

The palisaded portion of the Mantle site enclosed an area approximately 236 metres (north – south) by 140 metres (east - west), covering a maximum area of 29,100 square metres (2.9 hectares) during the early phase of occupation. The main occupation area within the early phase palisade was 220 by 130 metres (2.5 hectares) (Figure 6), while the main occupation area within the late phase palisade was 195 x 125 metres (2.0 hectares) (Figure 7), not including the cemetery.

Since the settlement plan of the Mantle site is significantly more complex than any Iroquoian site excavated to date in the Lower Great Lakes, unravelling the occupational history of the village involved the development of innovative means of analysis. In order to understand transformations in the occupational history of the Mantle site as a whole, the entire village was sorted into “early” and “late” stages based on the first and third (or final) phases of the palisade.<sup>1</sup> Since the construction, deconstruction and relocation of structures would have been on-going processes, some longhouses were assigned to the early and late phases, and/or the early-mid or mid-late phases, reflecting the idea that they were occupied throughout or part way through the duration of the occupation of the village.

Multiple criteria were used when assigning a longhouse to a particular phase, including: a) superimposition of, and fit within, palisade phases or with features, longhouse alignment and distance from adjacent houses; and b) the density of wall posts and features, both of which are known to be time-dependent (Finlayson 1985; Johnson and Jackson 1980; Warrick 1988). When possible, longhouses with similar orientations and spacing were grouped together and placed in the same phase. The superimposition of longhouses on other longhouses, palisades or features was used to determine the order of construction or deposition (particularly when one structure had already been assigned to a particular phase). The proximity of structures to one another and to palisades was also used to determine which ones were contemporary with each other. In summary, multiple lines of evidence (i.e., superimposition, alignment, proximity to other structures, and wall post density) were used to sort houses into phases.

Where possible, attempts have been made to associate features with houses. However, because some houses occupied spaces that may have been exterior areas either before or after the construction or demolition of a house, some features that appear to be associated with houses may in fact be exterior features from another phase of occupation. For example, the many features that are situated in the proposed plaza area (see Section 2.5.1 below) are likely associated with that plaza and not the superimposed houses that also occupied that space. The feature database (Appendix B) lists the house associations for features that were found within longhouses, regardless of the phase to which either one belonged.

The density of posts in house walls was used to estimate the length of time that houses stood and/or were occupied, which helped to gauge the temporal relationships and contemporaneity of houses. The basis of this interpretation is the assumption that long-lived structures would have significantly higher wall post densities as a result of repair and rebuilding than short-lived or semi-permanent structures. Houses with similar geographical alignment and similar wall post density might therefore be contemporary structures. The density of posts per linear metre of house wall was calculated by measuring undisturbed segments of house wall (which were assumed to be representative of the entire structure), counting the number of posts in those segments, and dividing this number by the metres in each segment to produce a figure for the average number of posts per metre. This reduced the potential for counting errors where house walls overlapped or were disturbed. House ends often contain fewer posts than walls and therefore do not provide an accurate measure of post density.

<sup>1</sup> The second palisade phase was omitted from this phasing because no structures or key features crossed it and, because the first, outermost palisade constructed on the east side of the village was contracted very early in the site's occupation.

There is a distinct difference in settlement pattern between the early and late phases. Early phase houses in the northern half of the site are oriented approximately east-west, perpendicular to the top of the east bank of Stouffville Creek. Early phase houses in the southern half of the site are arranged in a radial pattern with the centre or focus being an open area located on the east side of the site.

Both practical and social explanations can be advanced to explain the arrangement of structures. Since the topography in the northern half of the site is relatively flat, the houses were perhaps oriented with consideration to the top of the creek bank or perhaps to mitigate environmental factors such as westerly winds or snow accumulation patterns. The land slopes down to the south, and the houses in that area were arranged so that a consistent perpendicular orientation to the slope is maintained. This arrangement also provided an “open” space in the eastern-central portion of the site during the early phase of occupation, interpreted as a “plaza” area. Such a space would have provided a venue for communal activities and events and may have served an important social and ceremonial purpose in the community (Birch 2010).

The late phase shows a much different settlement pattern. There are still some east-west oriented houses in the northern half of the site but there is a random character to the distribution of houses throughout the central and southern sections of the site. There does not appear to be a conscious effort to maintain an open common area as seen in the early phase; rather, houses were constructed within available spaces as other houses fell out of use or were dismantled. The total area of the palisaded portion of the site was reduced with the construction of the later palisade, which could explain the need to fit a house into any available space.

Table 1 illustrates which houses are associated with one of the two site perimeter palisades (early or late; also early-mid and mid-late where applicable), and it also lists the individual house measurements (including maximum excavated and estimated lengths). In some cases, because of successive longhouse expansions or contractions, it may not be possible to determine the phase during which the house was at its maximum length. The area given in Table 1 for each house represents the total walled area, rather than the results of a simple length/width formula. This was done in order to more accurately reflect the actual space enclosed within houses.

Table 1: Mantle Site Longhouse Variability

House	Site Phase	Length (m)	Width (m)	Area (m <sup>2</sup> )	Wall post density (pm/m)	Orientation (°E of N)

\* or a\* - refers to the shortest or narrowest version of the house visible; b\*\*/c\*\*\* - refers to the longer versions of the house, based on number of end walls visible; <sup>†</sup> - refers to the estimated length, width and/or area; Inc. stands for Inconclusive and indicates that there was not enough data to produce an accurate measurement.

## **2.3 House Descriptions**

### ***House 1***

House 1 was the northernmost house at the site and was located between the two main palisades and north of the trench midden (Feature 709) (Figure 6). It was oriented 95° east of north and measured 42.9 metres in length by 7.2 metres in width, providing an enclosed area of approximately 271 m<sup>2</sup> (Table 1). The western end wall was rounded, with a 4.2 metres wide opening (likely a doorway) at the centre of the end. The eastern end wall was slightly tapered with a few posts closing off the end.

The wall post density of House 1 averaged 2.9 posts per metre. The walls were formed primarily by single a row of posts; however, there was a tight clustering of posts at the east end of the south wall (Figure 8). The higher density of posts in this area may have been the result of repair or re-building of walls. The distribution of interior posts did not reveal a pattern resembling a bunk line, but these posts were probably related to other household activities. Seven pit features along with five support posts were located in the house.

House 1 was assigned to the early phase of site occupation because it was located within the outer palisade, but outside of the (late phase) inner palisade (Figure 7).

### ***House 2***

This house was situated six metres southeast of House 1 and just over two metres north of House 6 (Figure 6). As with House 1, it was located between the two main palisades and north of the trench midden (Feature 709). It was 15.6 metres in length and 7.4 metres in width with an enclosed area of 102 m<sup>2</sup>. The orientation of this house was 109° east of north (Table 1). Both ends were rounded with a 2.6 metres wide opening in the southeast end that could have been a doorway.

The walls of this house contained an average of 3.4 posts per metre and were mainly formed by a single row of posts (Figure 9). However, the density of the wall posts varied around the perimeter of the house. The highest density was in the south wall while the lowest was in the northwest area of the house. There was a row of interior posts located 1.85 metres from the south wall oriented parallel to that wall. These posts may have been part of the interior framing for a bunk line along the south wall. The rest of the posts found in the house could have been related to house activities or may have been structural. Four pit features were contained within the house.

House 2 was assigned to the early phase of the settlement because it lay outside the late phase palisade (Figure 7).

### **House 3**

This house measured 37.6 metres long by 5.5 metres wide (Table 1). It was the second narrowest house on the site after House 23, which was 5.4 metres wide. House 3 was oriented 93° east of north and covered an area of 201 m<sup>2</sup>. It was located 1.3 metres south of and oriented parallel to House 1 (Figure 6).

House 3 was situated directly over an east-west section of the inner late phase palisade (Figure 8). The density of wall posts, taken from the undisturbed north wall, averaged 3.6 posts per metre.

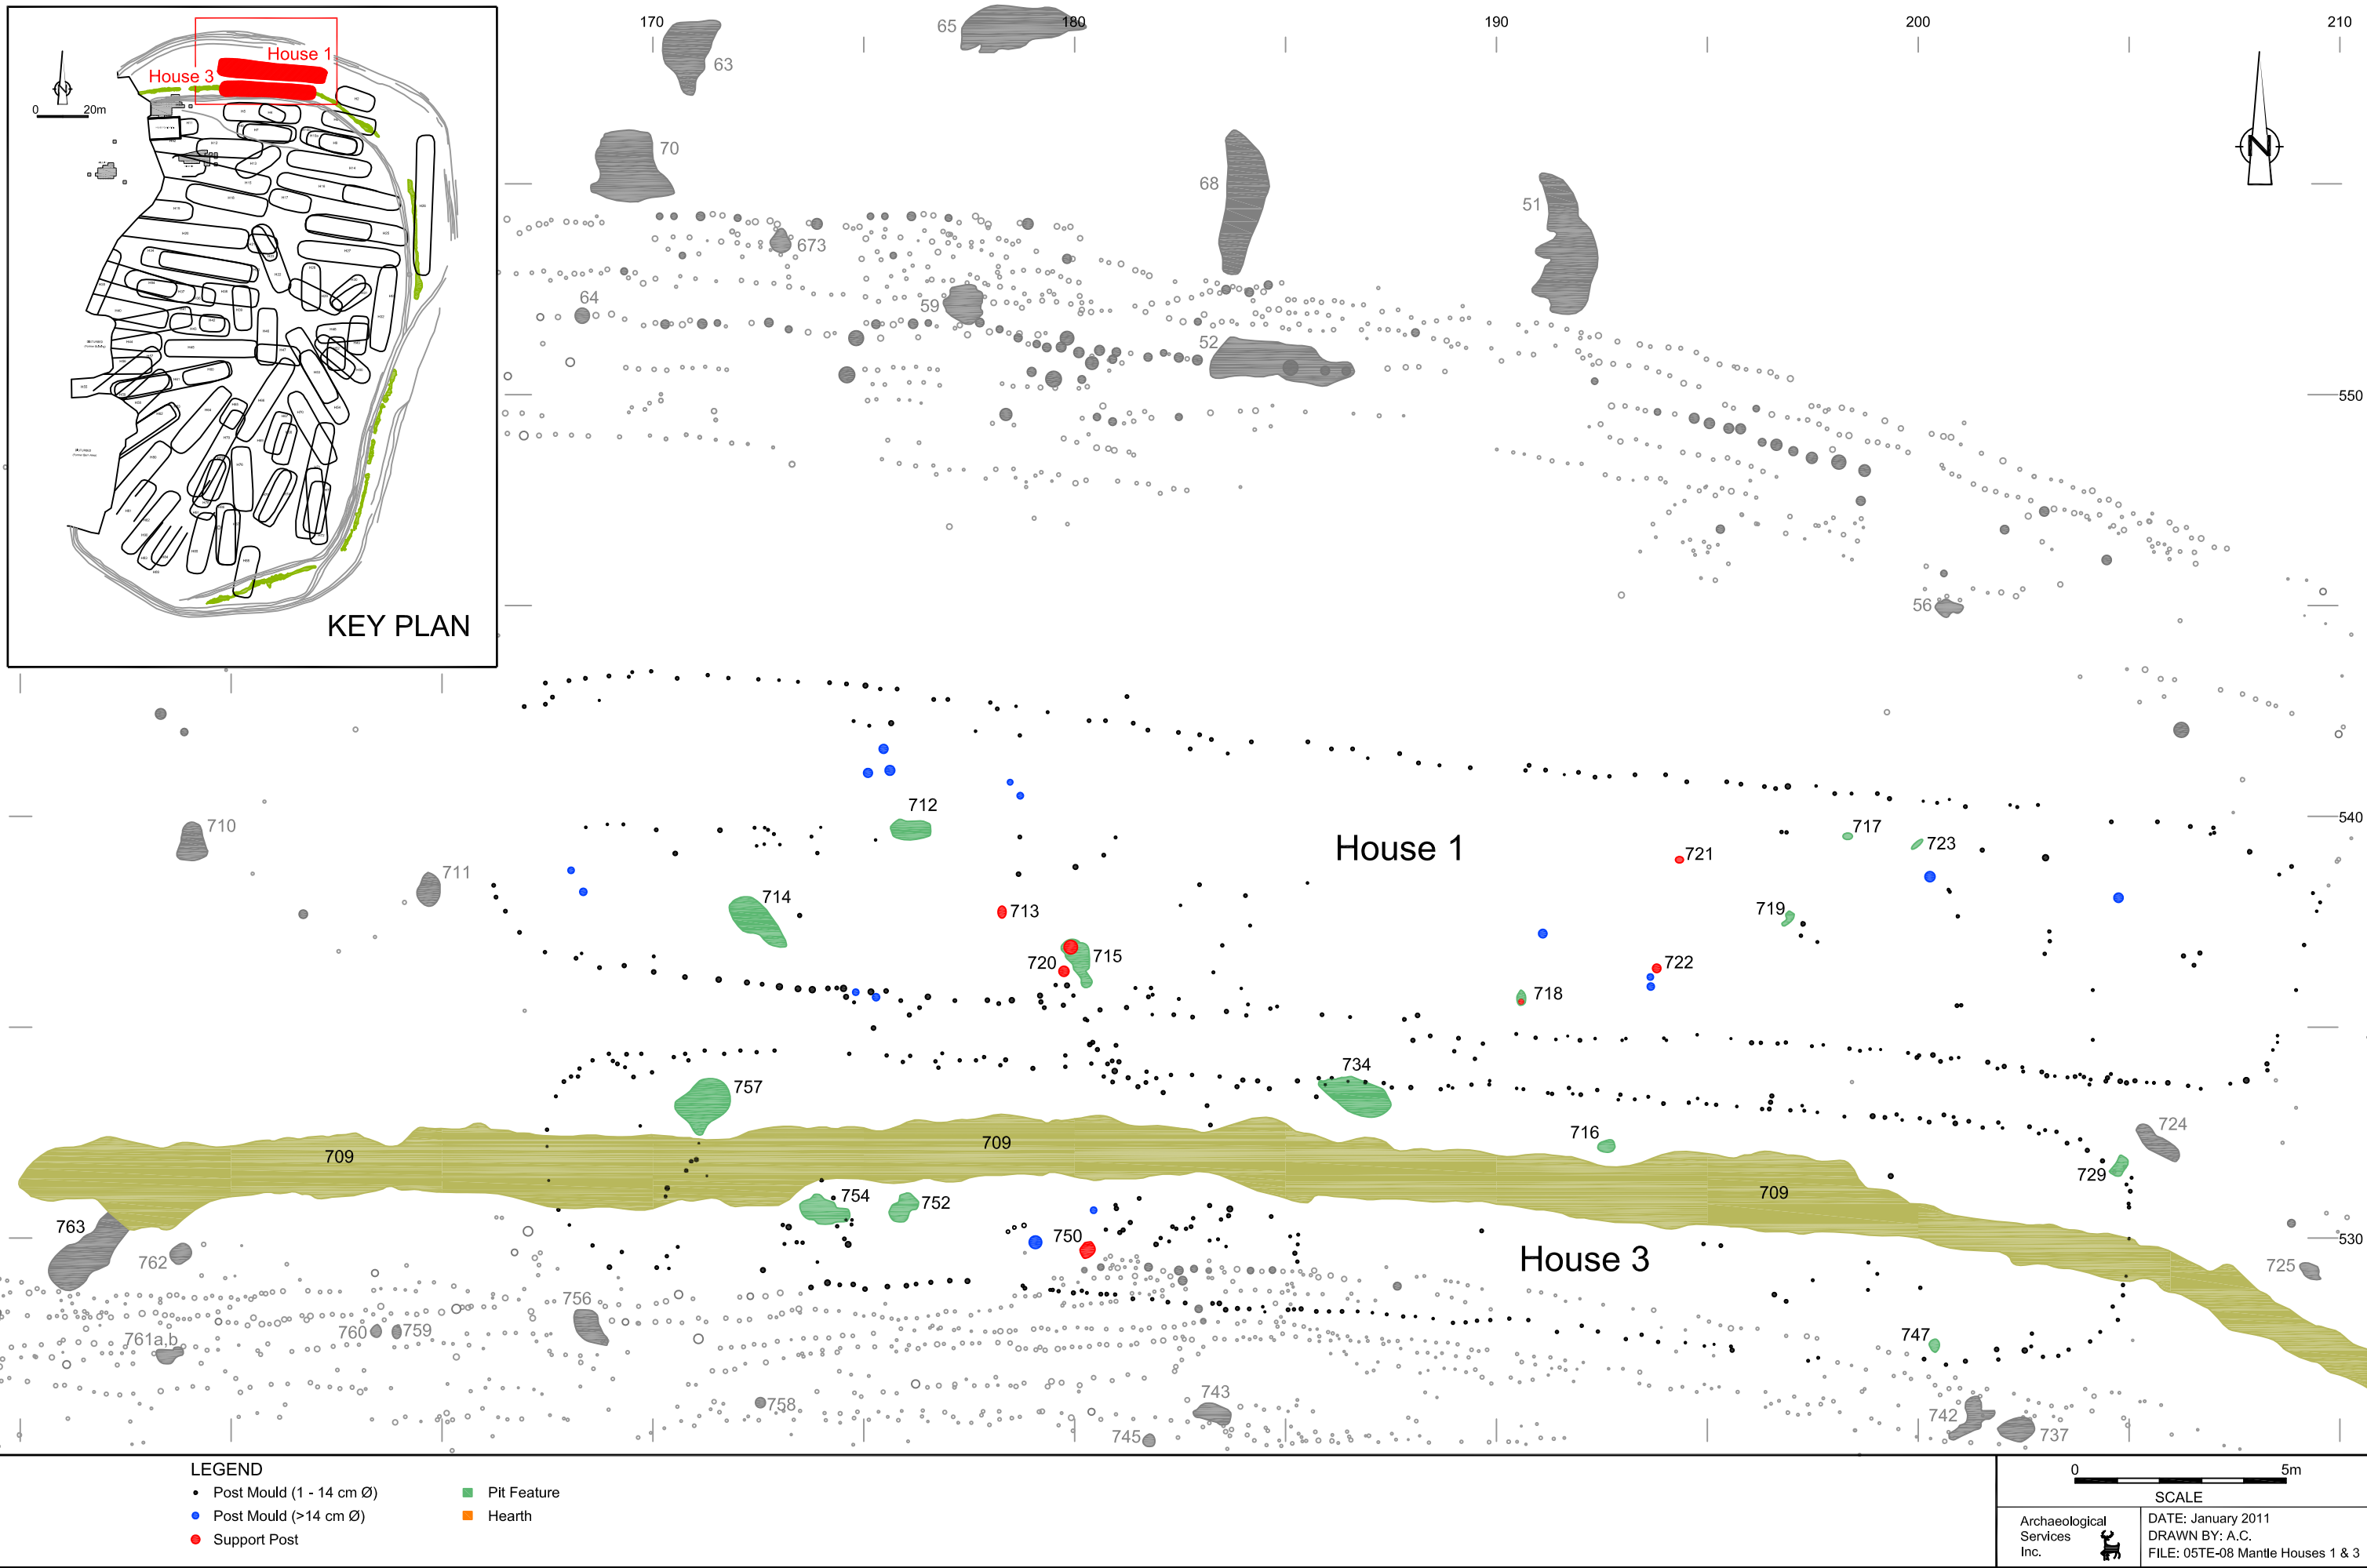

Figure 8: Plan View of House 1 and 3

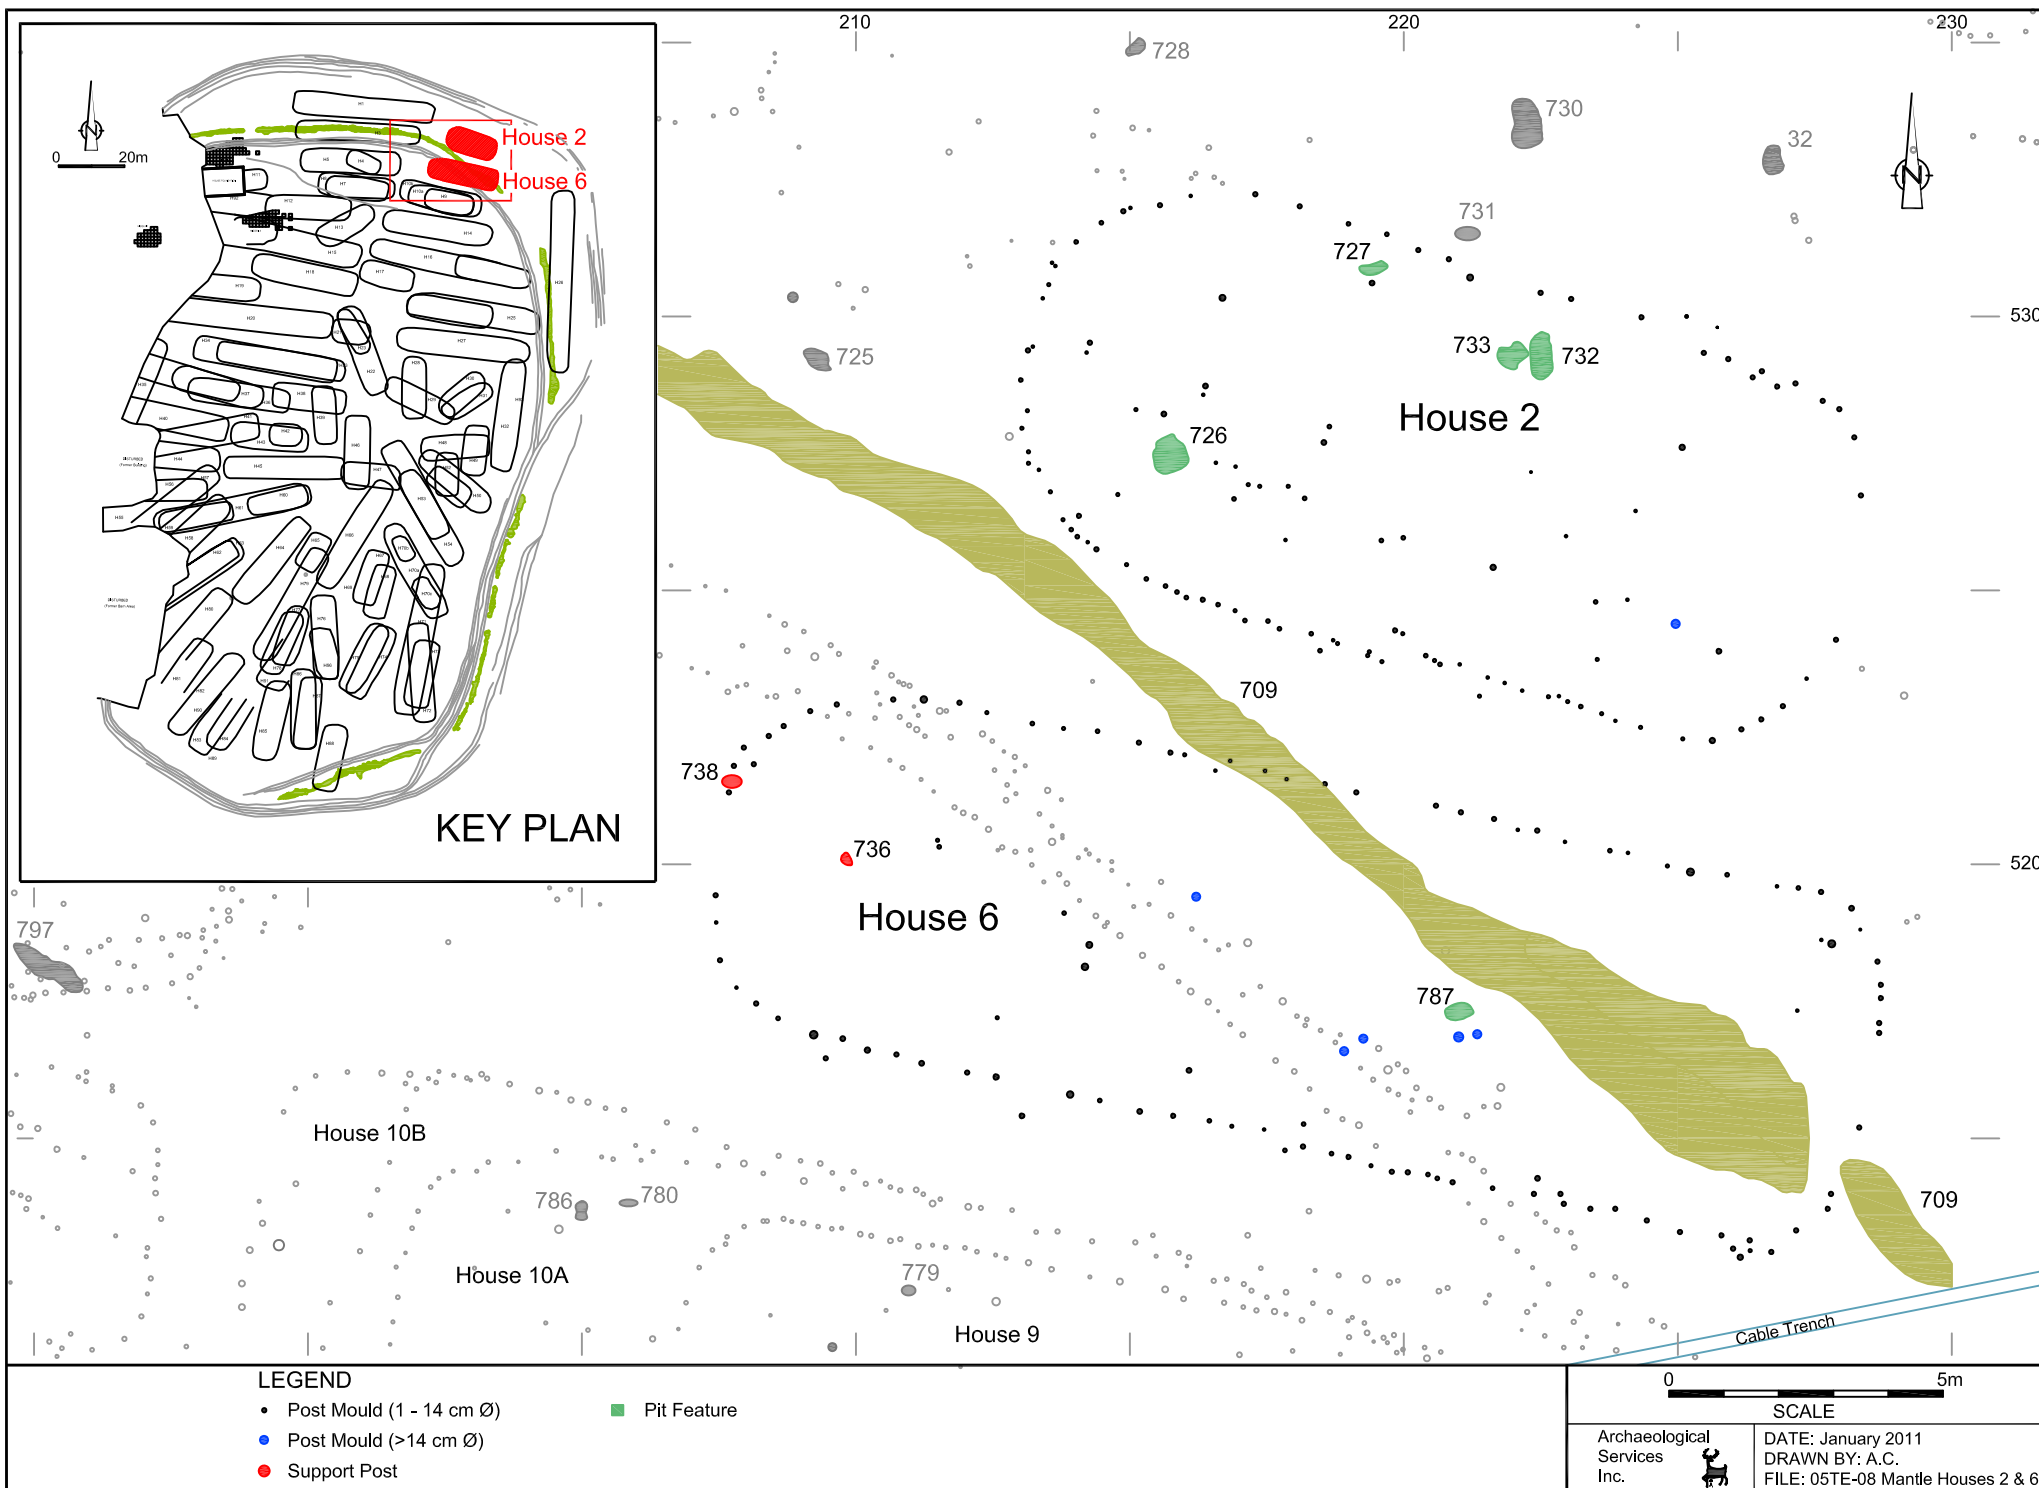

Figure 9: Plan View of House 2 and 6

Average house wall post diameters, post row alignment and post spacing/patterns were used to determine which posts in the area overlapping the palisade were used for the south wall of House 3. Feature 709, the trench midden, runs directly along the central axis of this house (Appendix B). Since the midden and the house could not have coexisted, and since the midden is associated with the late occupation phase of the village (see section 2.6), House 3 is therefore thought to have been part of the village's early phase (Figure 7).

Seven pit features and one support post were excavated in this house. Other smaller posts found in house were most related to activities within the house. Some posts may have been placed for structural purposes, but the pattern is inconclusive.

## **Houses 4 and 5**

House 4 was found within the building footprint of House 5, which was located approximately 3 metres south of House 3 (Figure 6). House 4 was 13.5 metres long and 6.3 metres wide, enclosing a total area of 73 m<sup>2</sup>, and it was oriented 100° east of north (Table 1). House 4 had an average wall post density of 4.1 posts per metre and was constructed using posts placed in a single row, although the north wall has sections of paired wall posts. There was a 1.6 metre wide gap in the north wall, which may have served as a doorway (Figure 10).

House 5 was 30.2 metres long and 6.9 metres wide, covering an area of 206 m<sup>2</sup> (Table 1). The house walls averaged 4.0 posts per metre with a variety of wall post placement patterns (Figure 10). There was pairing and clustering of posts throughout the middle sections of the north and south walls. The ends of the house rounded with flat ends. Possible doorways were identified at the east and west ends, with one and two metre wide openings, respectively. Bunk lines were not identified, but there were rows of post in areas of the doorways. These may indicate the presence of structures that were used to control and enclose the entrances to this house.

There was a concentration of features in the area of House 4 that overlapped with the east half of House 5 (Figure 10). Since there were very few features found outside the walls of House 4 within House 5, the majority of the features found in these two houses were probably associated with House 4. Six pit features, six support posts and a hearth were identified in House 4, while the internal area of House 5 excluding the area within House 4 contained six pit features and two support posts. It is possible that some of the support posts in House 4 were part of the House 5 structure. It is difficult to assign any of the features to either House 4 or 5, but the clustering within House 4 suggests that many of those features were contemporary with House 4. Given that the orientation of House 5 is similar to that of Houses 1 and 3, it was likely part of the early site phase (Figure 6). Therefore, House 4 was most likely occupied during the late phase of the site (Figure 7).

## **House 6**

House 6 was located just over two metres south of House 2, overlying sections of the late phase palisade and its associated trench midden (Figure 7). It therefore belonged to the early phase of site construction (Figure 6). The orientation of this house was 102° east of north, which is very similar to Houses 1, 2, 3 and 5 (also built during the early construction phase).

House 6 was 21.5 metres in length and 6.6 metres wide enclosing an area of 135 m<sup>2</sup> (Table 1). The house walls had only 1.8 posts per metre, suggesting a very short or low-intensity occupation. The walls were constructed by placing posts in a single row with openings at each end (Figure 9).

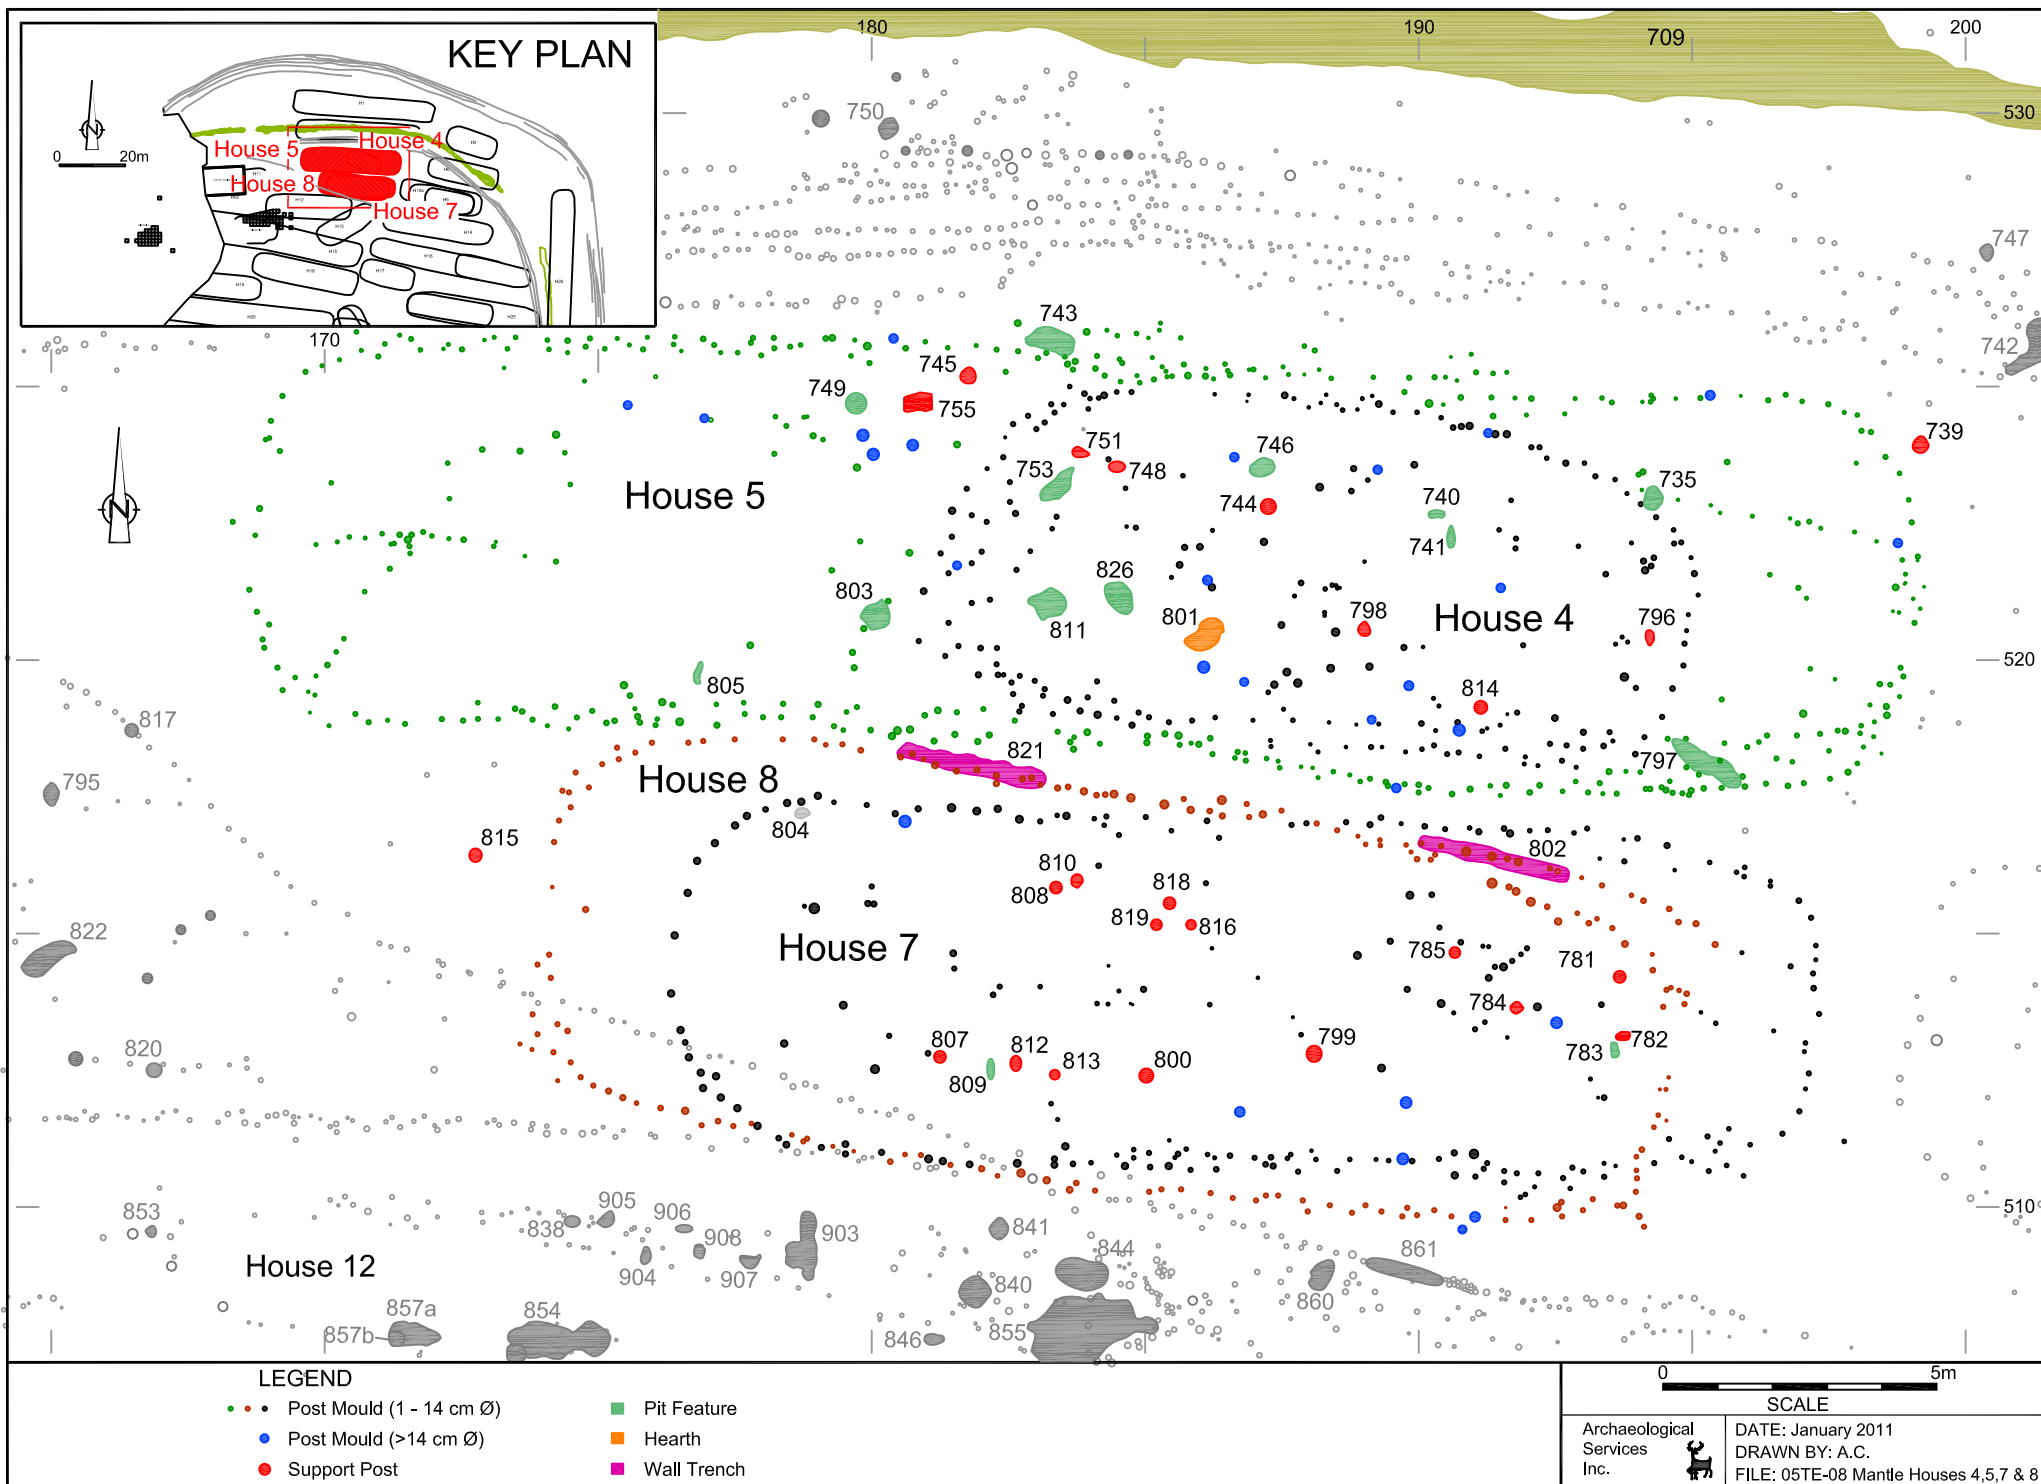

Figure 10: Plan View of Houses 4, 5, 7 and 8

The opening at the west end was 1.8 metres wide and the opening at the east end was 1.7 metres wide. The west end was rounded in plan view and the east end was rounded with a flat end. One central pit feature was located in the east half of the house, and two support posts were located at the west end of the house. The pattern of the other interior posts was not regular enough to suggest that they were part of the framing of the house.

### **Houses 7 and 8**

House 7 was located 0.8 metres south of House 5 at an orientation of 92° east of north (Table 1). House 8 overlapped this house and came within 0.2 metres of the south wall of House 5 (Figure 10). Since House 7 was almost parallel with House 5 and House 8 nearly touched House 5, it is probable that House 7 was built during the early phase of the site (Figure 6) and House 8 was built in the late phase (Figure 7). Given the similar outlines and orientations of both houses, it may be that House 8 was built to replace House 7.

House 7 was 20.9 metres long and 6.3 metres wide covering an area of 124 m<sup>2</sup> (Table 1). The west end of the house was rounded and the east end was tapered. There was no clear doorway, but the larger spacing of posts at the west end of the house could have accommodated a doorway. The wall post density of House 7 averaged 3.1 posts per metre. Walls were formed by a single row of posts, with the exception of the south wall that displayed some clustering of posts (Figure 10).

House 8 was the same length as House 7 (20.9 metres) but slightly wider (6.9 metres), and it enclosed an area of 139 m<sup>2</sup> (Table 1). As with House 7, the wall posts were placed in a single row, but there was post pairing in the south wall and a greater density of posts was observed at the ends. The average density of wall posts was 3.8 posts per metre. Each end of the house had a 1.2 metre wide opening, which suggests the placement of doorways (Figure 10).

Since all features were contained within the overlapping area of Houses 7 and 8, it was not possible to assign a particular feature to a particular house. Nonetheless, it is unlikely that a large post would be placed in the east end doorway of House 8, which means that post feature 782 might have been part of House 7 (Appendix B). Two pit features, fourteen support posts and one ash pit were uncovered in this area. It is not clear which support posts belonged to House 7 and which belonged to House 8.

### **Houses 9, 10a and 10b**

These three houses overlap each other with House 9 located completely within the footprint of House 10a and most of 10b (Figure 5). Houses 10a and 10b have sections of the south walls sharing the same location. It is clear that these three houses had to exist at different times so it is necessary to place one of them in a middle or transitional occupation phase.

House 9 is 81 m<sup>2</sup> in area with a length and width of 14.7 metres and 6.1 metres, respectively (Table 1). This house was constructed using a single row of posts, but it also had a clustering of posts along the south wall towards the east end (Figure 11). The average density of wall posts was 2.9 posts per metre, and the west end was rounded and the east end was rounded with a flat end. A doorway may have been located in the middle of the south wall where there was a 1.6 metre wide opening. One pit feature, three support posts and one hearth were contained in this house, but they could have belonged to House 10a or 10b as well.

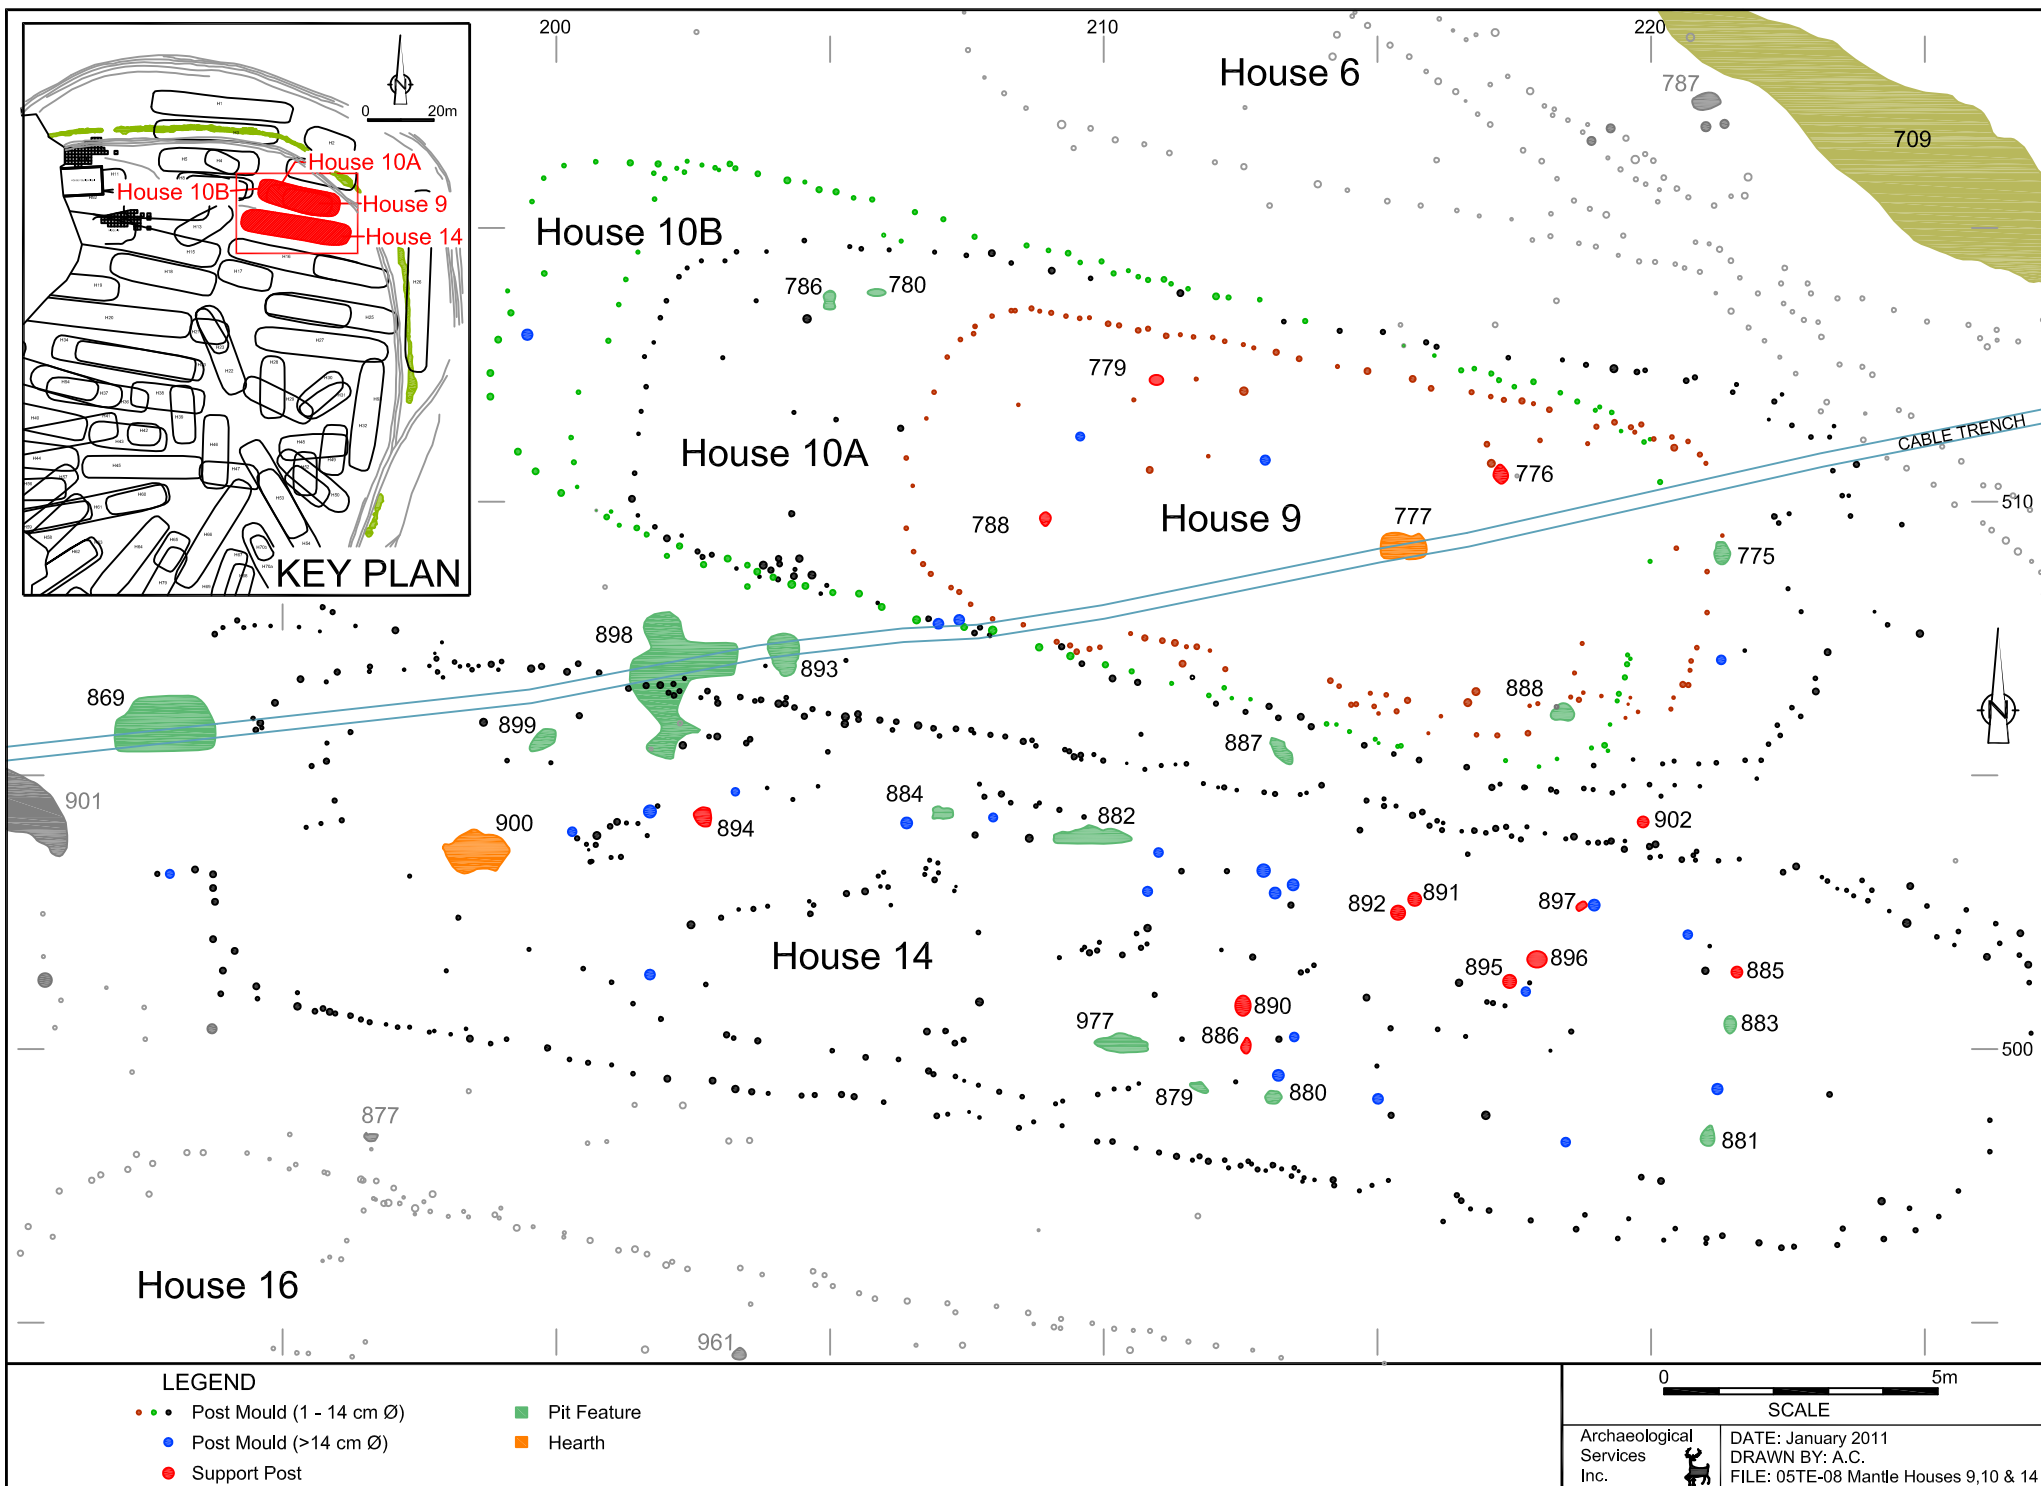

Figure 11: Plan View of houses 9, 10a, 10b and 14

House 10a was located just west of the late phase palisade and approximately 2.5 metres south of House 6 (Figure 7). The northeast corner of the house slightly abutted the palisade, so that there was no separation between the two structures (Figure 11). Since there was a separation of houses from palisades throughout the rest of the site, it is likely that this house antedates the late phase palisade and should be assigned to the early phase (Figure 6). House 10a measured 22.2 metres long and 6.9 metres wide, enclosing an area of 150 m<sup>2</sup> (Table 1). The wall posts for this house were placed in a single row with a 2.5 metre wide opening at the east end. The wall post density of House 10a was 2.6 posts per metre, a low average, but the south wall may have been shared with House 10b and the density was markedly higher on this side, perhaps a result of the rebuilding of House 10b (see below). The house had slightly rounded ends, the east end more so than the west. Three pit features were found within House 10a. Feature 775 was located beyond the east end of House 10b, outside of House 9 but within House 10a, so it was probably associated with this house. Features 780 and 786 could be contemporary with either House 10a or 10b because they are situated inside both houses (Appendix B).

House 10b was 21.3 metres long and 7.0 metres wide and covered an area of 143 m<sup>2</sup> (Table 1). The wall posts averaged 3.0 posts per metre and were placed in a single row (Figure 11). At the west end of this house there are two possible ends. If the inner end represents the first west end of the house, then original house length was 19.3 metres. If these two ends existed simultaneously, they could have formed the framework for a vestibule or enclosed entrance, with the 1.6 metre wide gap located in the westernmost end forming the doorway. With the exception of Feature 775, all of the features identified as being within the boundaries of this house could be contemporary with it (Appendix B).

House 10a has been assigned to the early occupation phase of the site because it abutted the late phase palisade. Therefore Houses 9 and 10b were part of a later occupation of the site (Figure 7). Since 10b was similar in size and orientation to 10a, it should be placed in the mid-to-late transitional phase and House 9 should be placed in the late phase.

## **House 11**

This house was located in the northwestern area of the site (Figure 5). The west portion of this house was impacted by the excavation of the basement for the later, twentieth-century farmhouse and subsequent garden plots in this area. The remaining portion of the house is 7.1 metres long and 6.3 metres wide, with the remaining area of the house covering 39 m<sup>2</sup> (Table 1). The wall sections that remained were constructed by offset post pairs, while the end had single row of posts (Figure 12). The average density of wall posts was 4.3 posts per metre. There was no gap in the posts that form the east end of the house that would indicate an entrance at that end. Within this small section of the house, four pit features were found along with two large support posts. The length of this house can be estimated by assuming that the house continued up to the edge of the slope leading to Stouffville Creek. If this was the case, the length of the house would have been 21.0 metres and it would have enclosed 114 m<sup>2</sup>.

The orientation of this house was 81° east of north. Even though House 11 had been truncated by the later farmhouse, it is clear that the west portion of the house would have overlapped House 92, which was probably built in the early occupation phase of the site (see below). Assuming that these two houses overlapped, House 11 was later than House 92 and should be assigned to the late occupation phase (Figure 7).

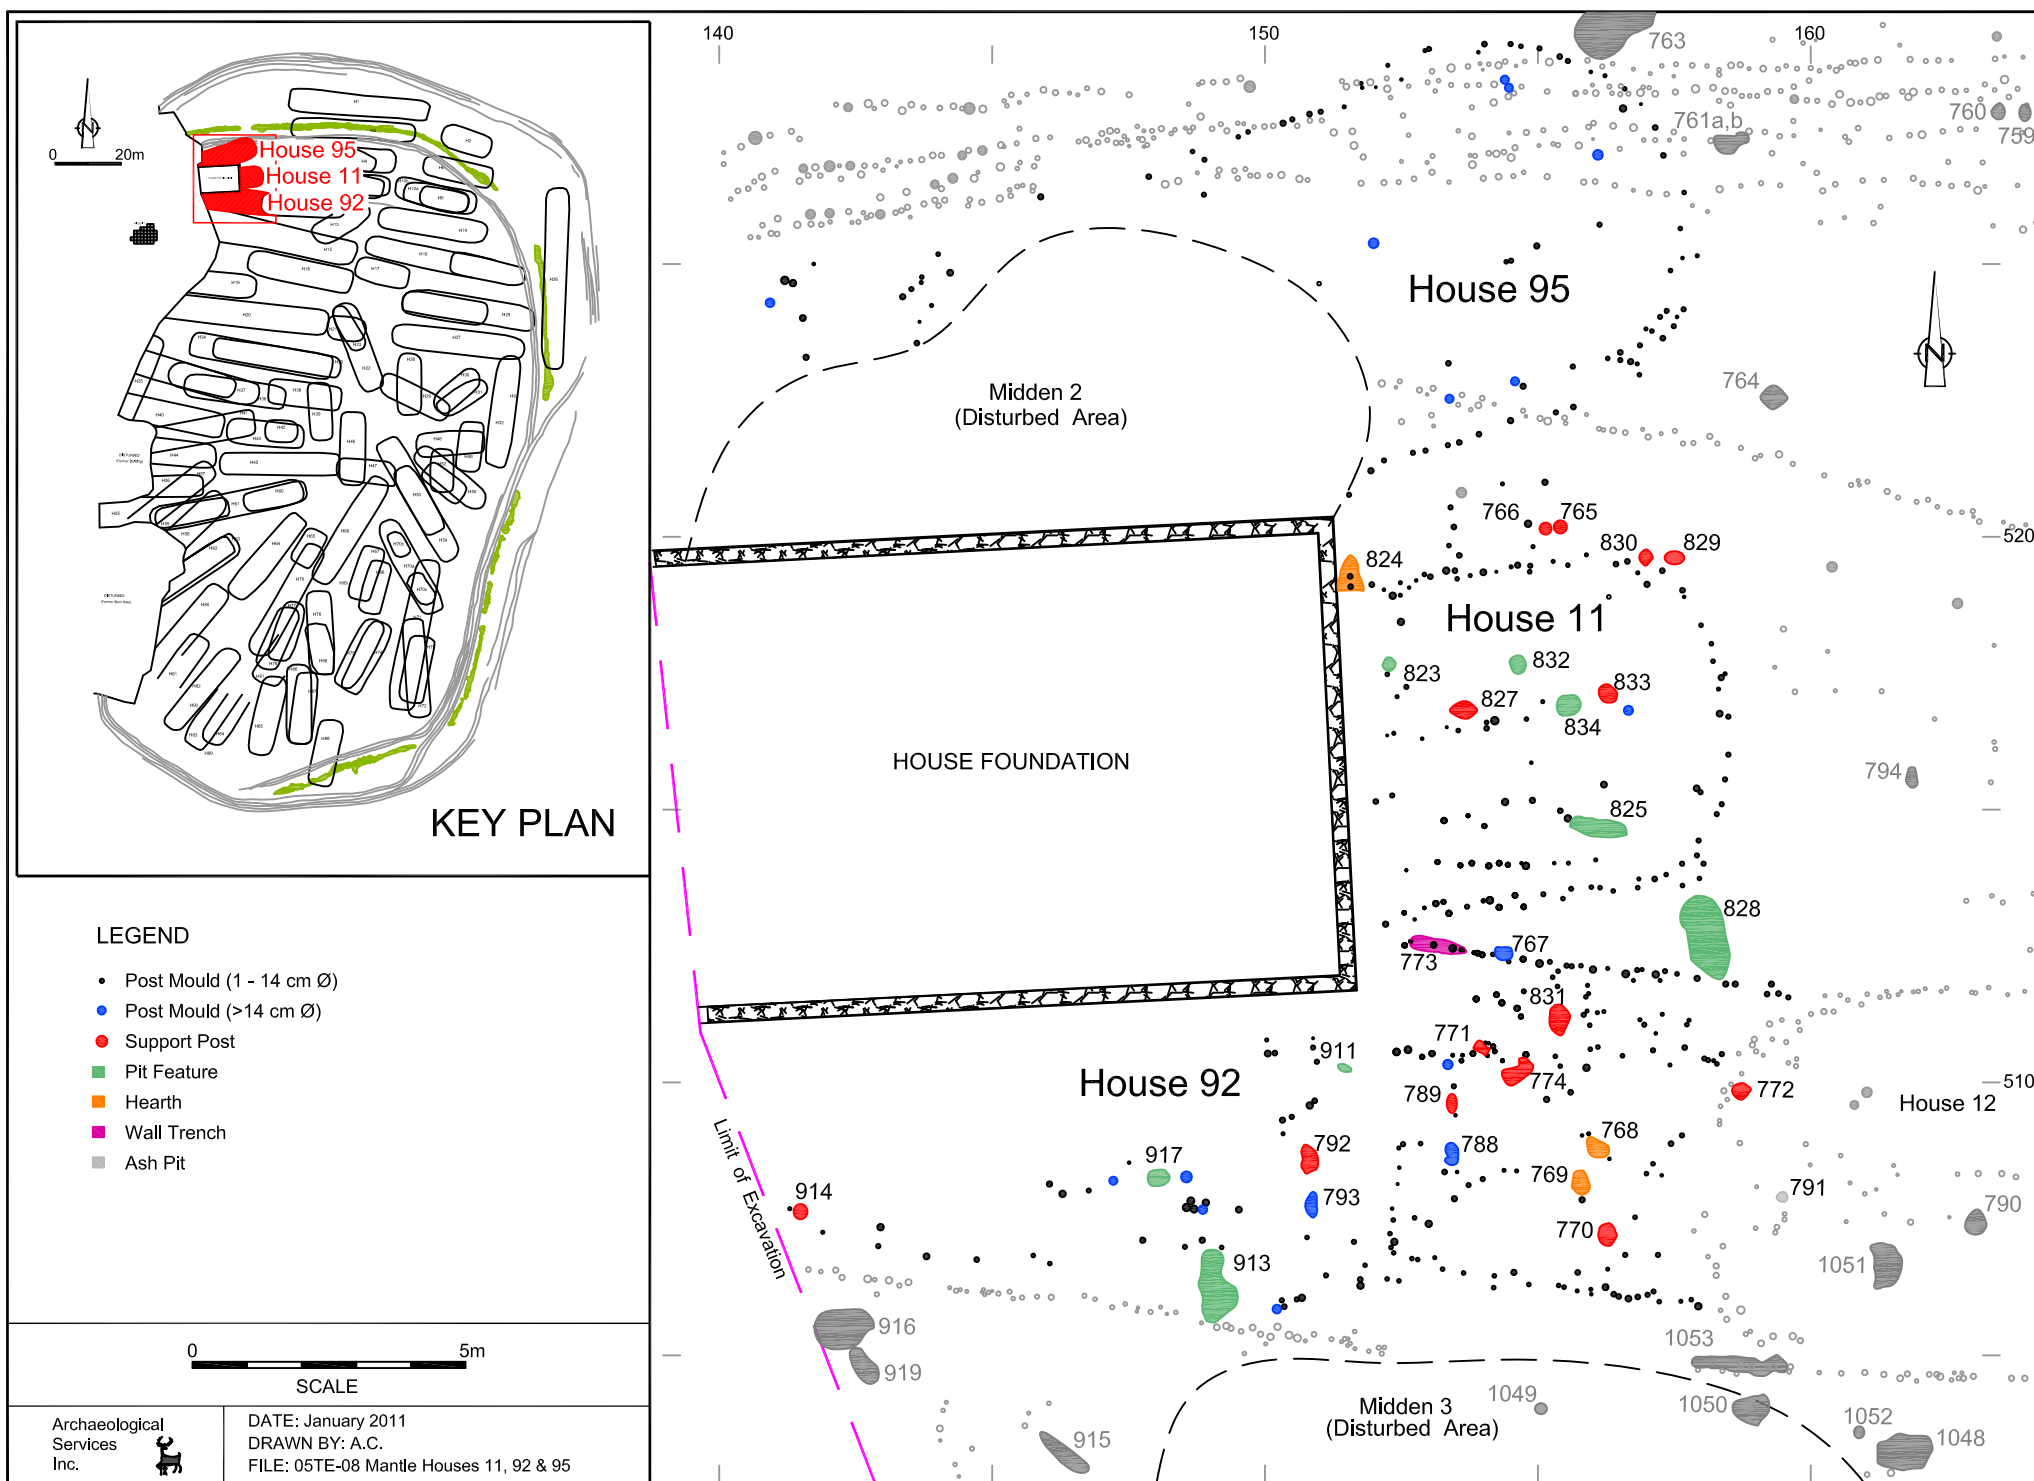

Figure 12: Plan View of House 11, 92 and 95

## House 12

House 12 was adjacent to the south walls of Houses 7 and 8 and east of House 92 (Figure 5). The north wall directly touched the south walls of those houses, so it is possible that this house did not exist at the same time as the other two. It is also possible that these houses were simply constructed with abutting walls. House 12 clearly overlay early phase House 92, and it appears that the occupation of this house erased any evidence of the east end of House 92 (Figure 13). Therefore, House 12 must have post-dated House 92, even though were probably in the early phase of the site's occupation (Figure 6). House 92 may simply have been constructed slightly earlier. This is not improbable considering that this area of the site was the longest occupied. This area of the site is also located on the most desirable land on the highest topographic point in the village (see also House 13 below).

House 12 was 25.8 metres long and 7.3 metres wide enclosing an area of 173 m<sup>2</sup> and oriented 92° east of north (Table 1). The walls were constructed by placing the posts in an offset pairing pattern, and they had an average density of 5.9 posts per metre, indicating a long occupation with significant repair and rebuilding (Figure 13). There was a clustering of posts along the south wall towards the east end that was probably the result of wall repair or strengthening. Both ends were rounded in shape with a 1.6 metre wide gap in the west end. This gap could have been a doorway, and it appears to have been the only one for this house.

Twenty pit features, one ash pit, two hearths, six support posts and a living floor area were contained within House 12. Pit features 844 and 855 were intersected by the east end wall of the house, so they are probably not contemporary with this house. Both hearths were found in the central area of the house along the central axis. There was a clustering of posts near the hearths that may indicate that there were racks or cooking structures over the hearths. The living floor was a thin, irregular shaped feature found in the east half of the house. It was composed of darker soil with a high concentration of organic matter (Appendix B).

A linear arrangement of interior posts was found 1.6 metres south of the north wall (Figure 13). These posts may have been part of the interior structural framing of the house, and may have formed a bunk line along the north side of the longhouse. Another alignment of posts was found along the central axis near the possible doorway in the west end. These could have been placed there for structural purposes as well as to frame the entrance to the house.

## House 13

House 13 was oriented 56° east of north and measured 18.7 metres long and 7.3 metres wide covering an area of 122 m<sup>2</sup> (Table 1 and Figure 5). The walls were made up of a single row of posts, except the southeast wall, which had some post-pairing (Figure 13). The average wall post density was 5.4 posts per metre, and the ends were rounded. Many interior posts were found throughout this house showing no clear pattern except for a single row of posts parallel to the southeast wall. This row was 0.85 metres from the wall and was likely part of a bunk line along that wall. The rest of the posts were concentrated at the two ends of the house. No clear doorway was observed in the ends, but there was a 1.7 metre wide gap located in the middle of the northwest wall.

Feature 855 (a large pit feature) and Feature 876 (a living floor) were both associated with House 12 (Appendix B). These features are superimposed over the north wall of House 13. All of the House 13 wall posts associated with these features were found below the features, in sterile subsoil but not in the fill of the feature or cutting through the living floor of House 12. As such, we can be sure that House 13 pre-dates House 12.

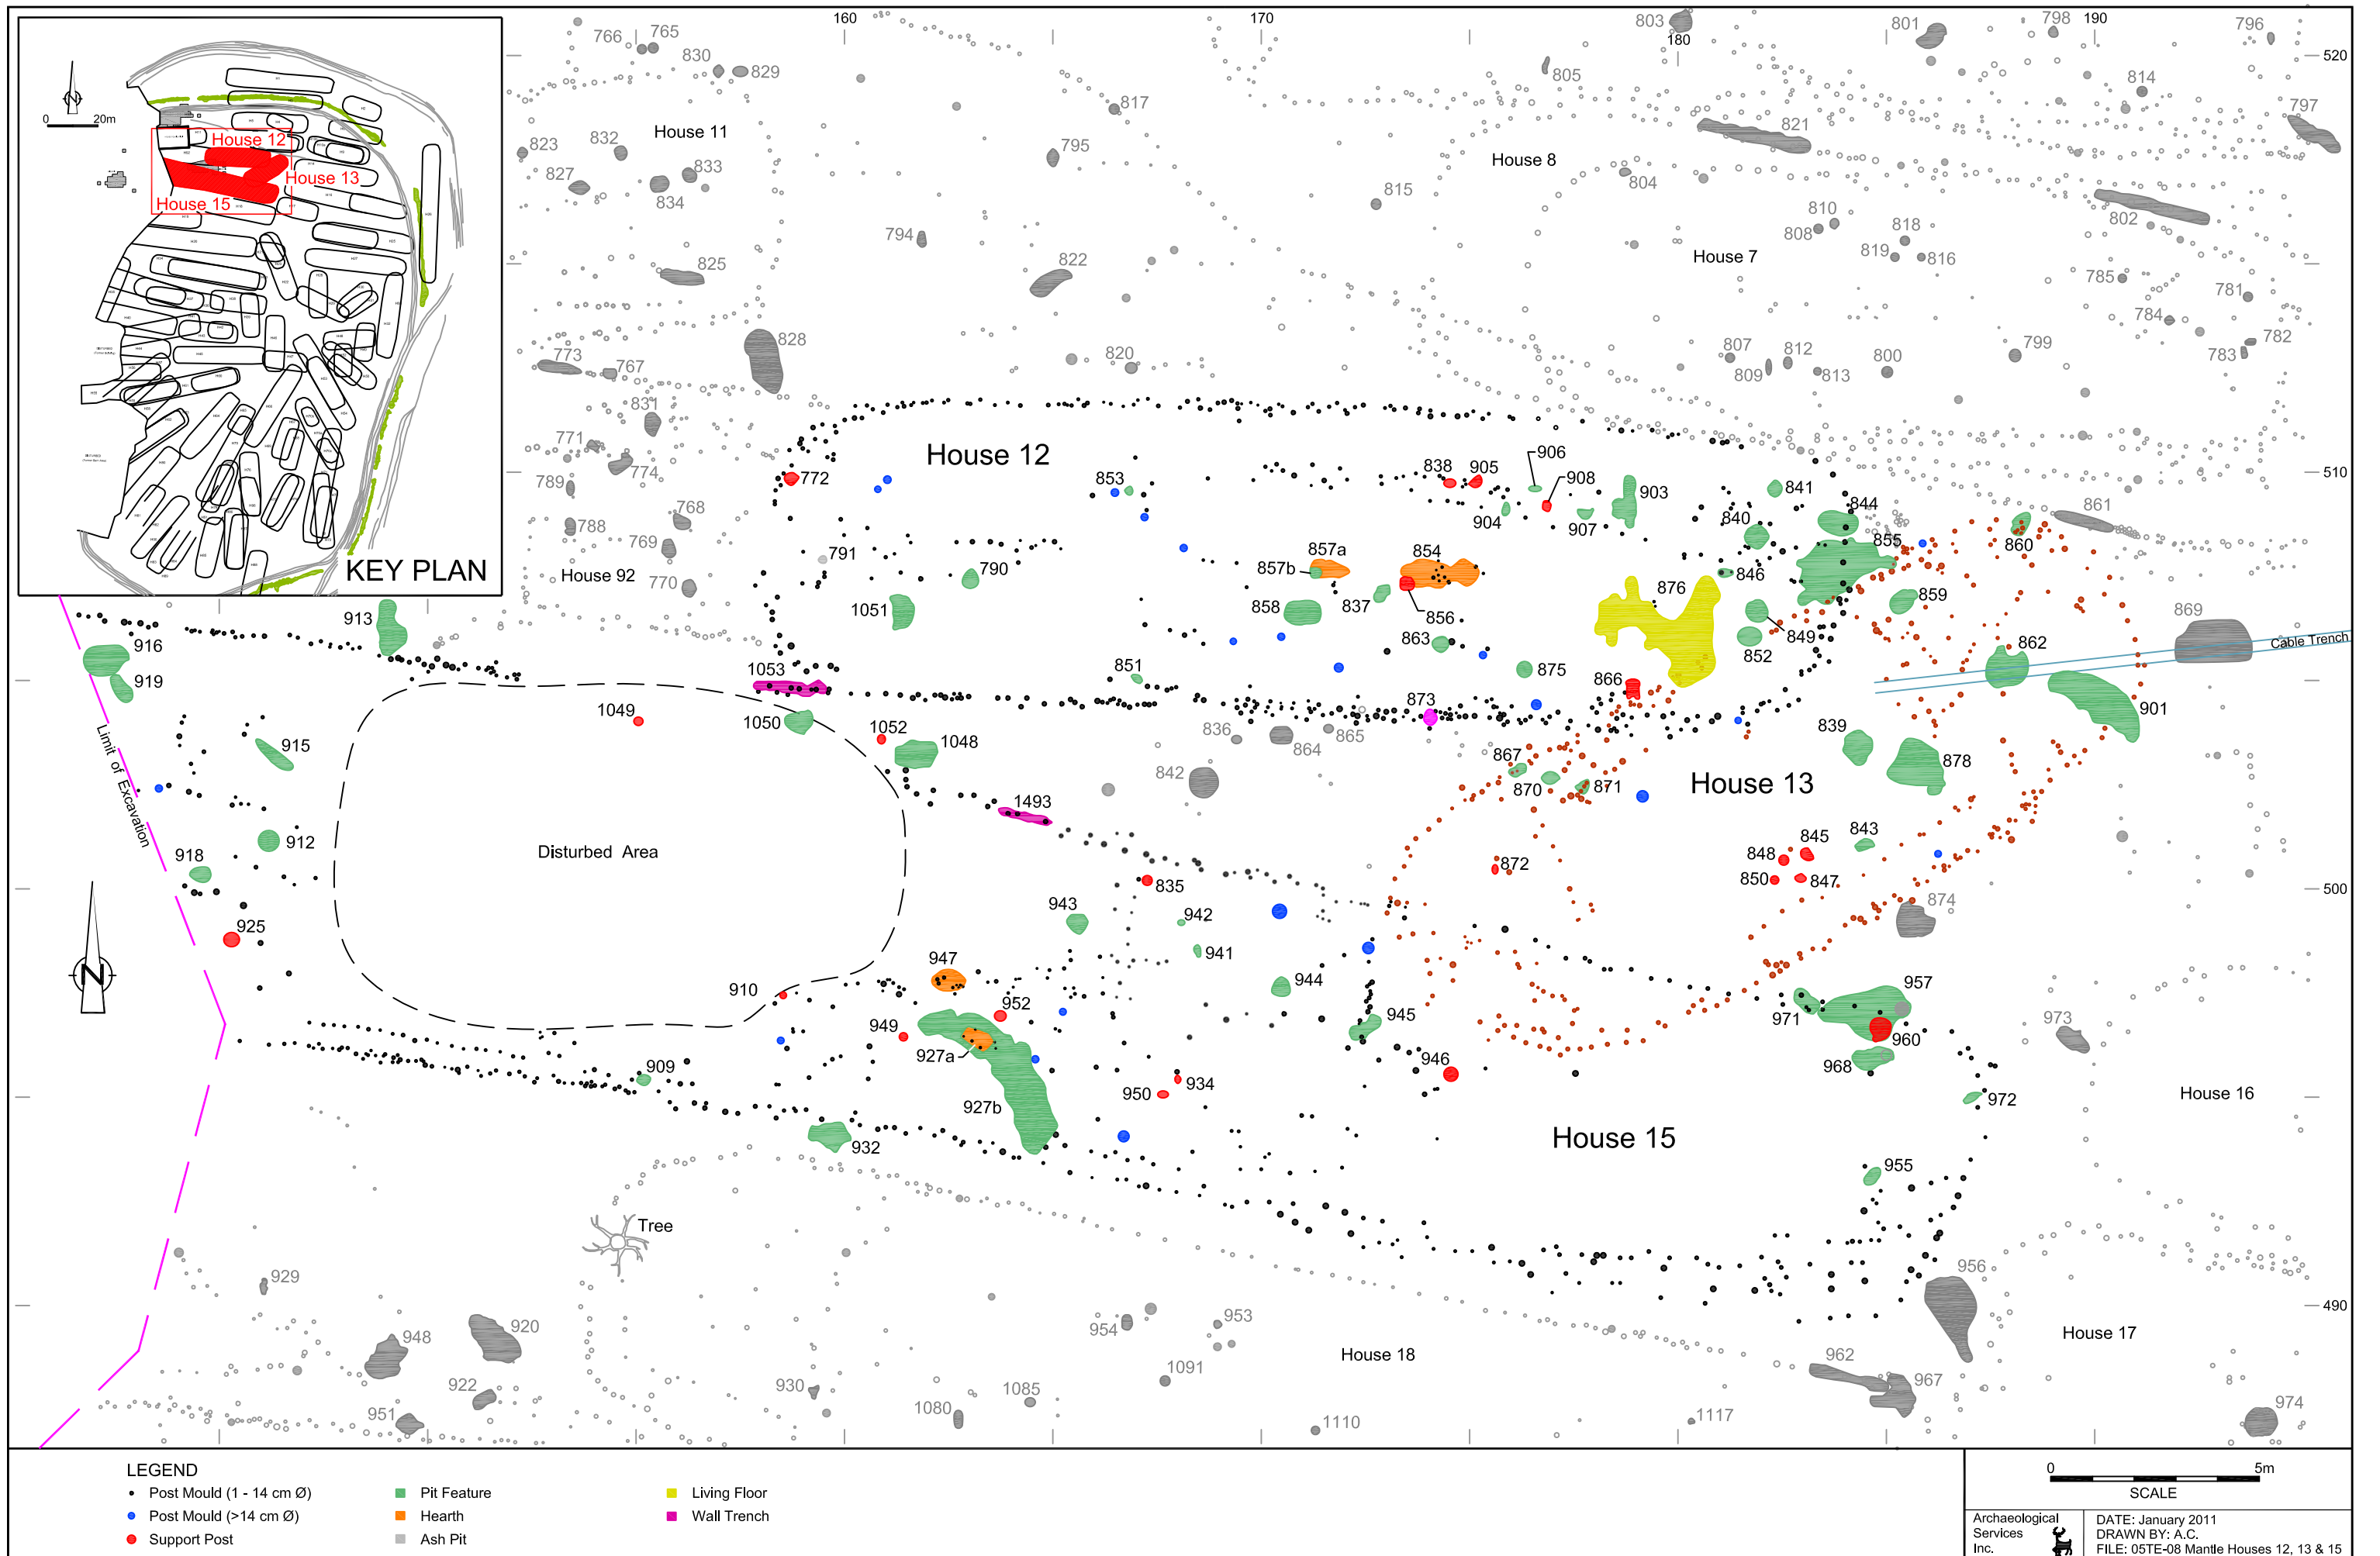

Figure 13: Plan View of Houses 12, 13 and 15

Given the association between House 12 and the group of houses in the northern part of the village, it is likely that House 13 pre-dates this group and may pre-date the early village (Figure 6). As such, it may have been constructed in order to provide shelter for the individuals charged with the task of preparing the site for occupation (see also House 26, which may have served a similar function). The dearth of features associated with the central portion of the house suggests that this house may have been occupied during the summer, as is believed to have been the case with House 26. All features located in or around House 13 appear to be the result of outdoor activities related to the later houses surrounding this area (Figure 13). Furthermore, it may be the case that this house survived into the early phase of the village, prior to the construction of Houses 12 and 15, as 15 may have been lengthened after its initial construction.

Five support posts and ten pit features were found in this house. Features 860 and 901 are intersected by the house walls and are therefore probably not contemporary with the house (Figure 13).

### **House 14**

House 14 is part of the grouping of houses with an east-west orientation assigned to the early phase of occupation in the north part of the village (Figures 5 and 6). The orientation of this house was 99° east of north, which is similar to Houses 7 and 10a (92° and 100°, respectively). This house was located one metre south of House 10a and measured 33.5 metres long and 6.9 metres wide covering an area of 218 m<sup>2</sup> (Table 1).

The house was constructed by placing the wall posts in a single row, but there were some wall sections where post pairs were found. The average density of wall posts was 3.7 posts per metre. Both ends were rounded in plan view with a 2.4 metre wide doorway opening located in the middle of the west end (Figure 11). The shape of the interior post concentration was similar to the shape of the longhouse, with a gap of approximately one metre between the house walls and post concentration. This gap could represent the location of bunk lines on both sides of the house.

The presence of nine pit features, nine support posts and one hearth suggests that this house was occupied for several years. No houses overlap it, so it may have existed in the early and late phases.

### **House 15**

House 15 was not completely exposed as the west end was located beyond the new housing development setback (Figure 5). The length of the segment of the house that was exposed was 47.2 metres, with a width of 7.8 metres (Table 1). Based on topography and the location of Midden 1 at the west end, the estimated total length of this house is 55 metres. This is one of the largest houses on the site with the exposed portion covering an area of 370 m<sup>2</sup> (Figure 13). With an estimated maximum length of 55 metres, the total area could be as large as 446 m<sup>2</sup>. The house is oriented to an angle of 103° east of north which is similar to other early phase houses in the north part of the site.

The average wall post density of House 15 was 6.8 posts per metre, the third highest in the village (only Houses 20 and 64 had higher densities). The walls consisted of different post patterns, which suggests that this house was subjected to multiple episodes of re-building and repair during its long occupation. Single row post arrangement was evident in the north wall at the east end, while post pairings and clusters characterised the south wall. The concentration of posts at the east end of the house could be the result of a major repair to that area of the structure. The east end is rounded with a flat end, and is constructed of a single row of posts. No doorway gap was evident in this end, so perhaps there was a doorway at the west end (facing Midden 1) (Figure 13).

The middle section of the house was disturbed by later activities related to the farmhouse located in the northwest area of the site. A portion of the north wall, the post patterns, and likely several interior house features were lost due to this disturbance. A high concentration of fragmentary pottery and other material related to the site were found throughout this area, and these probably originated in the area of Midden 1 (or another midden located close to it). The construction of the farmhouse north of House 15 caused the disturbance to House 15 and nearby midden deposits. Five large mature trees were also located within the area over House 15, which affected the preservation of the features below them (Figure 5).

Many features and support posts were found in the walls of this house, including sixteen pit features, ten support posts and two hearths. Given the distribution of these features and support posts it is clear that others would have been located in the area of the house that was disturbed.

This house should be considered to be part of the early phase of the village; however, due to its size and complexity, it probably existed for the entire occupation of the site (Figure 6).

### **House 16**

House 16 was oriented similarly to House 15, at 101° east of north (Figure 5). It had a maximum length of 49.4 metres and width of 6.5 metres, covering a total area of 304 m<sup>2</sup> (Table 1). The east end overlaps the alignment of the late phase palisade and since it is assumed that the two structures were not contemporary, this house is assigned to the early occupation phase of the village (Figure 6).

At some point in the occupational history of this structure it was extended to the west by a considerable amount (Figure 14). The original structure measured 23.2 metres in length and covered an area of 142 m<sup>2</sup>. Another possible end made up of a single row of posts was observed 2.4 metres west of the first end. The house was then extended by 26.2 metres. The width of the house remained more or less the same, with some thickening of the walls where the extension joined the pre-existing structure. The average density of wall posts was 3.1 posts per metre. It should be noted that the overlapping area of wall construction shows a shift in wall placement of approximately 0.5 metres, even while the house width is kept the same. Every extension on this house seems to have been westward. Since the east end of the house lies beneath the late phase palisade and appears to have remained in the same place throughout the occupation of the house, it is probable that House 16 had been dismantled a) before the late phase of the village; and/or b) concurrently with the contraction of the village and the construction of the late phase palisade.

A distinct activity area within the house was observed in the vicinity of the four hearths (hearth features 980 to 983) (Figure 14). Hearths at Mantle are generally located along the central axis of the houses set back from the ends, which means that hearth feature 980 was not contemporary with the original west end of the house that formed the earliest and shortest version of the house (Appendix B). The many posts associated with each hearth indicate the presence of cooking structures.

Along with the hearths, six pit features, five support posts and one midden-like feature were found in this house. The midden-like feature contained organic refuse that would have been undesirable in a house, so this feature was likely created after the house was abandoned.

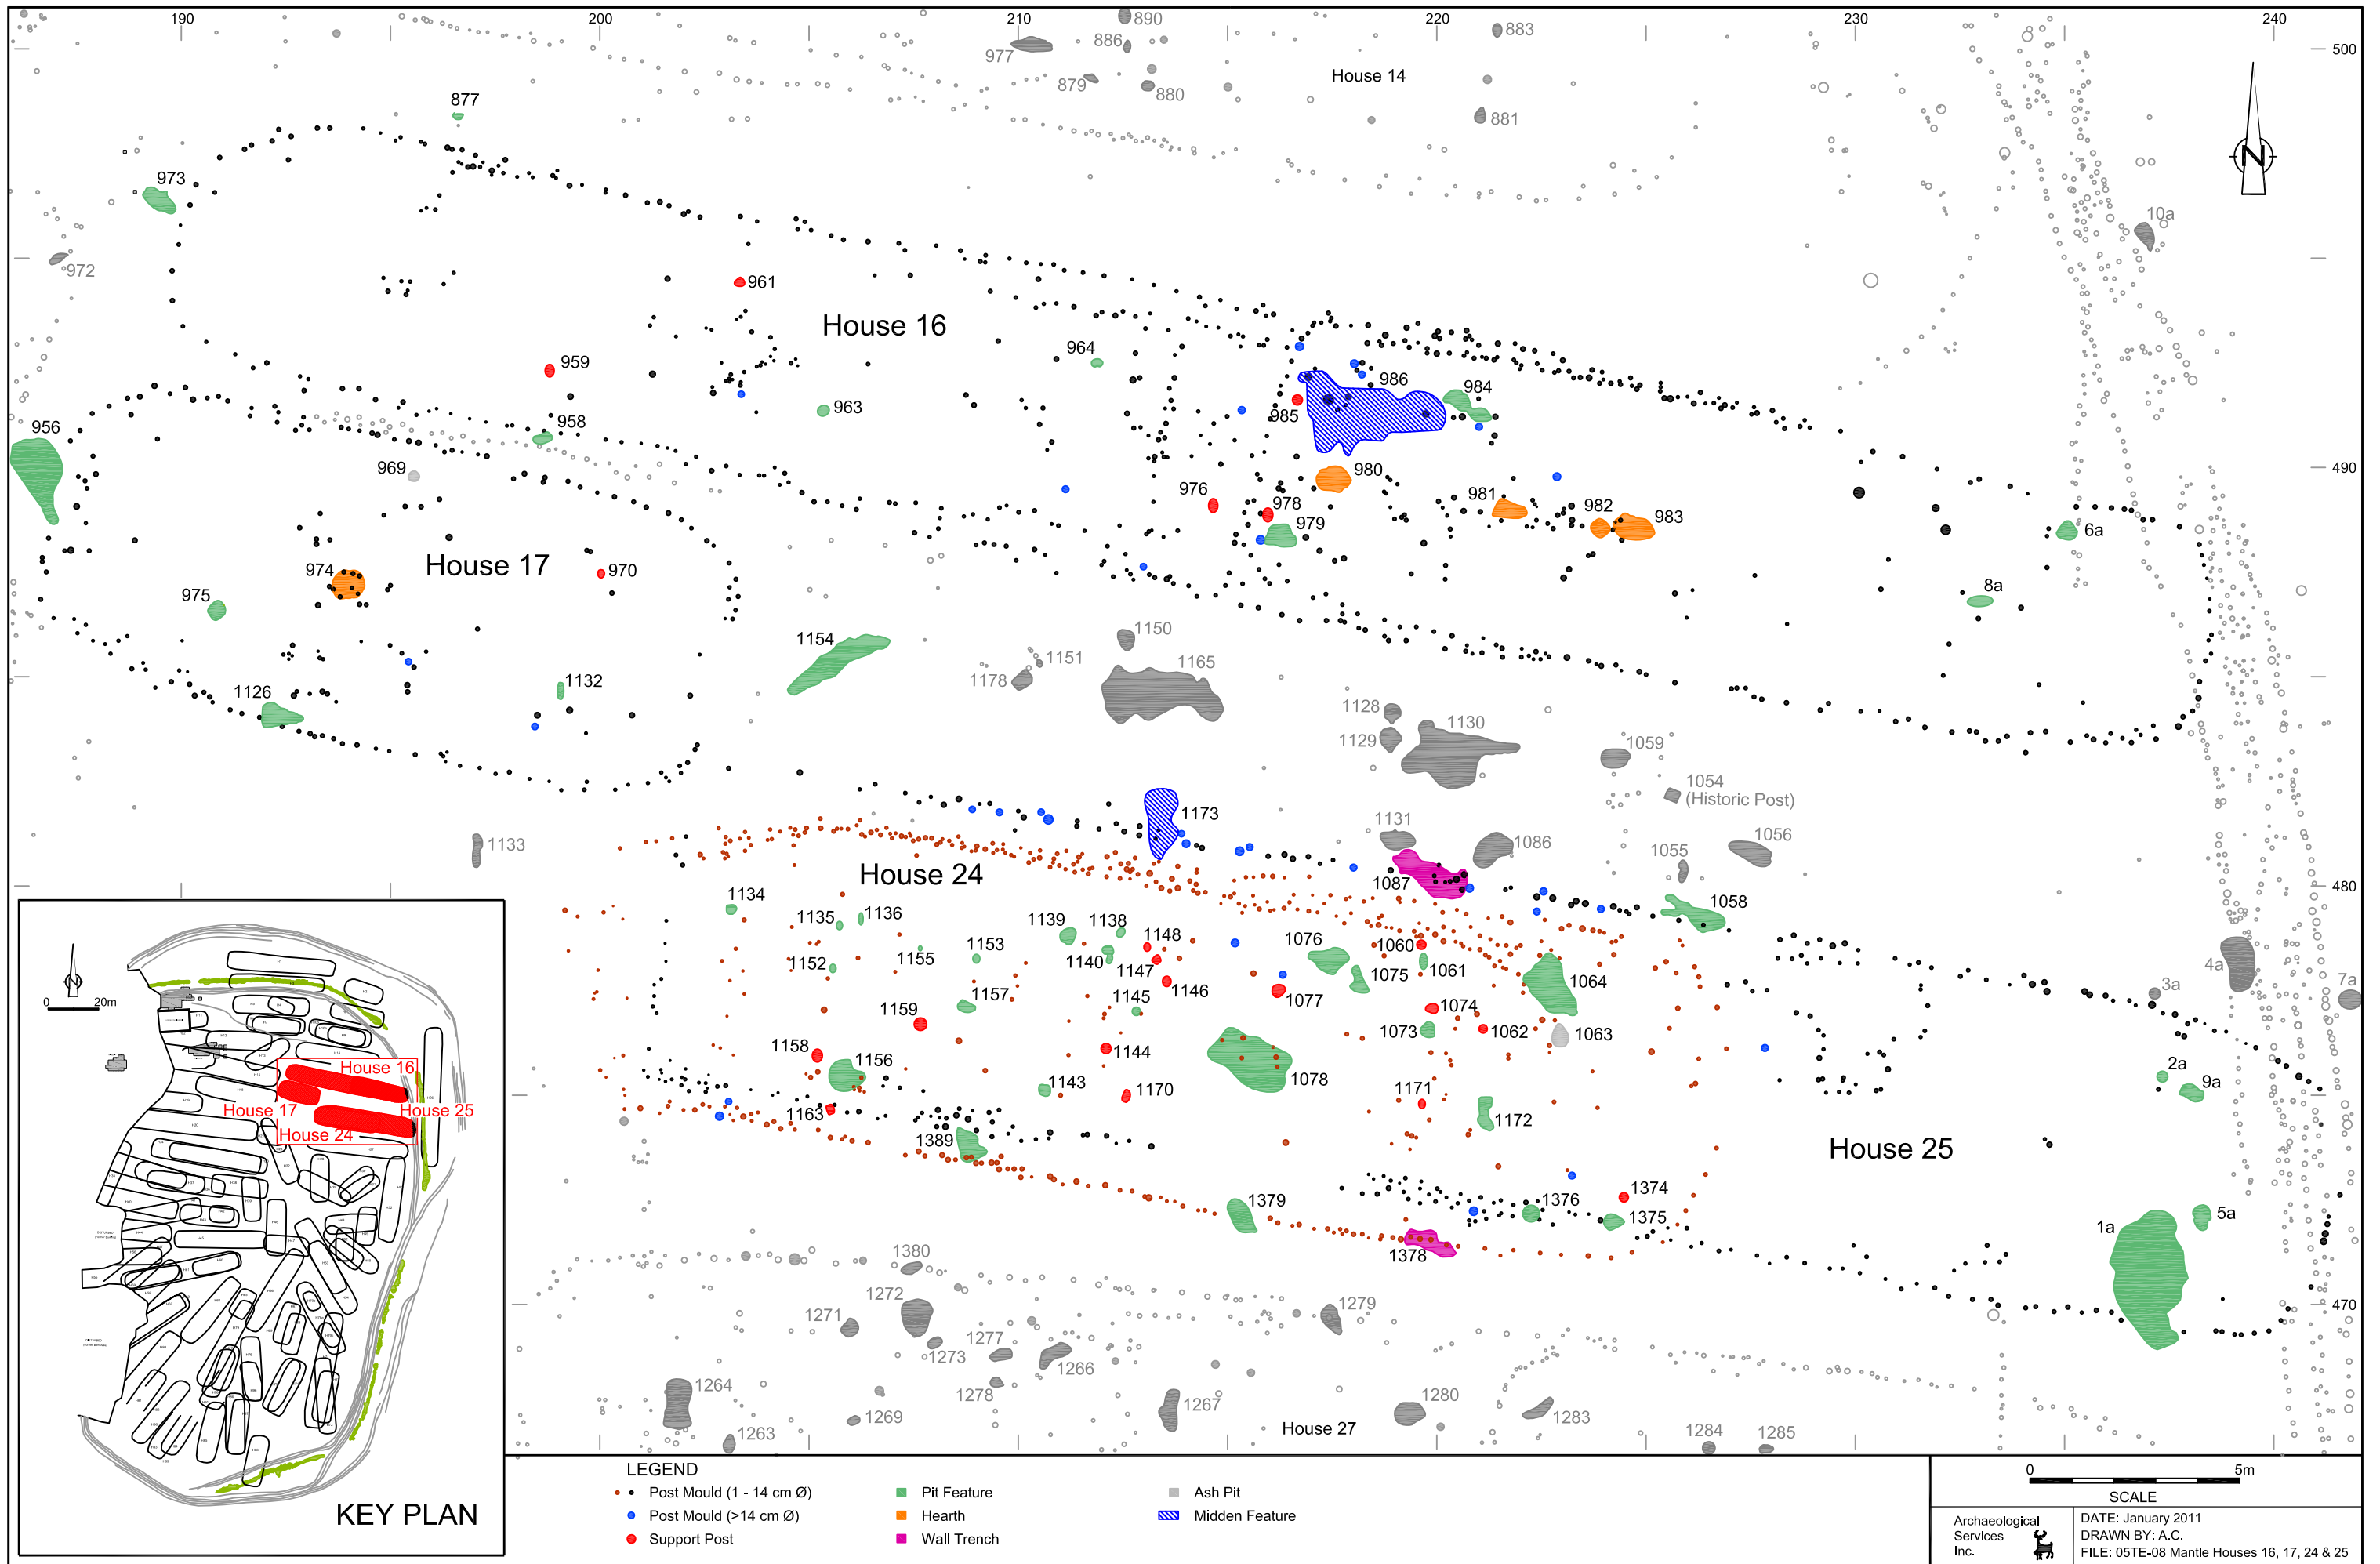

Figure 14: Plan View of Houses 16, 17, 24 and 25

**House 17**

House 17 was a relatively small house located 0.8 metres south of House 16 (Figure 5). It measured 16.4 metres long and 7.3 metres wide covering an area of 109 m<sup>2</sup> and was oriented at an angle of 103° east of north, almost parallel with House 16 (Table 1 and Figure 14). Given its close proximity and parallel orientation to House 16, House 17 should be considered contemporary with this house (early occupation phase) (Figure 6).

The walls of this house were constructed of a single row of posts except at the west end of the north and south walls where there was some doubling of posts. The average wall post density was 3.3 posts per metre. A distinct three metre wide gap in the east end and a 2.2 metre wide gap in the west end were likely doorways. The interior posts located within the house at the west end may have been used to form a barrier structure to separate the interior of the house from the doorway. The west end was tapered and the east end was rounded in plan view (Figure 14).

There was a single hearth (Feature 974) in the centre of the house surrounded by posts that likely formed a rack or cooking structure over the hearth. Three pit features, one ash pit and a support post were also present in this house. Feature 956, a pit feature, was found within the west end doorway, which suggests that it was not contemporaneous with the house (Figure 14).

**House 18**

House 18 was part of the group of houses located on the west side of the site oriented approximately perpendicular to the east bank and slope of Stouffville creek (Figure 5). This group includes Houses 92, 15, 18, 19, 20, 33, 34, 37, 40, 44, and these houses are considered to be part of the early occupation phase (Figure 6).

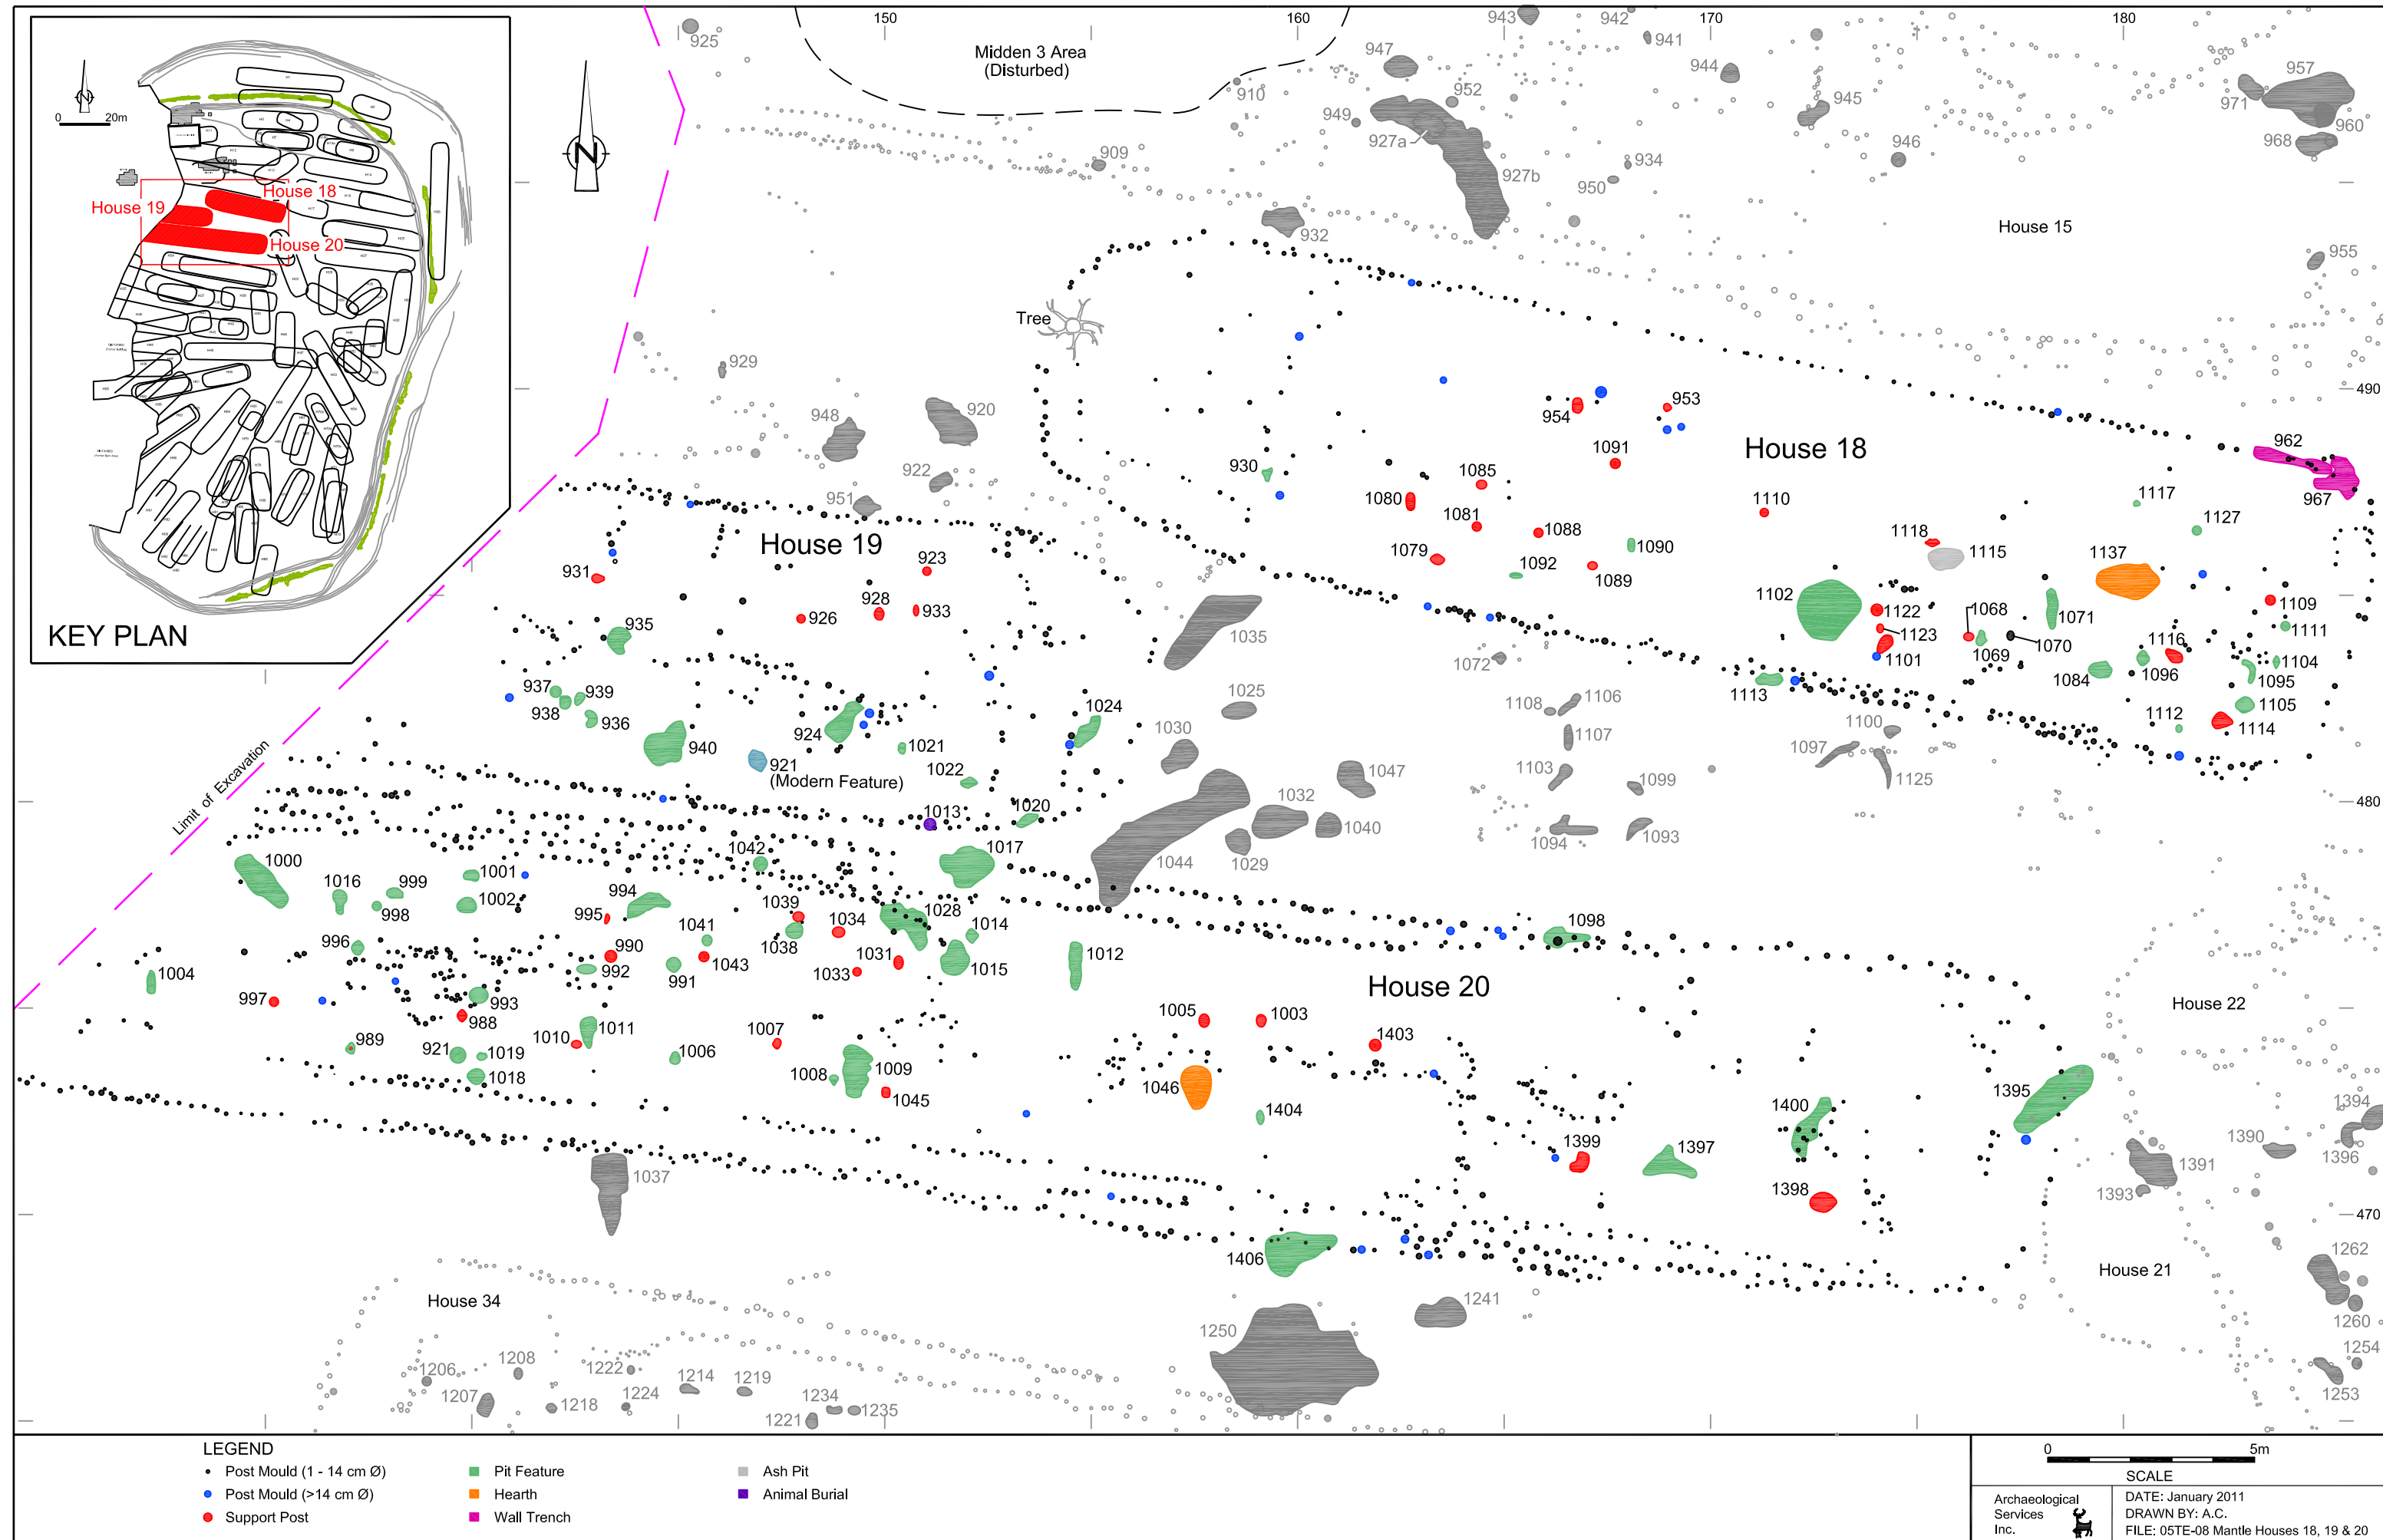

House 18 was located 1.25 metres south of House 15, and was oriented 101° east of north and almost parallel to House 15 (Figure 15). It measured 32.4 metres long and 7.6 metres wide enclosing an area of 236 m<sup>2</sup> (Table 1). A single row of posts was used to construct the walls and ends of the house, resulting in an average wall post density of 4.3 posts per metre. Additional wall posts along the south wall at the east end were probably the result of repair or rebuilding. The ends of the house were different shapes in plan view. The east end was squared off, while the west end was rounded. A 1.9 metre wide opening, probably a doorway, was observed in the west end of the house.

This house contained fourteen pit features, eighteen support posts, one ash pit and one hearth. There is a definite concentration of activity in the east half of the house: eleven pit features, nine support posts, the hearth and the ash pit were found in this half. Several interior house posts near the west end might have been part of an entranceway and used to separate the interior of the house from the doorway. A short row of posts parallel to the south wall and west end, and offset 1.9 metres from them, was also recorded in this area. A single hearth was found on the central axis of the house five metres from the east end wall (Figure 15).

Several of the houses occupied during the early phase survived into the late phase of the site. Along with Houses 15, 19, 20, 33 and 34, House 18 seems to have been one of the longest occupied houses in the village.

## House 19

The west half of House 19 was not excavated because it extended beyond the modern development setback and it was probably disturbed by the roadway running along the top of the bank for the farm complex (Figure 5). The exposed east section of the house was 20.4 metres long and 7.4 metres wide covering an area of 125 m<sup>2</sup> (Table 1). Based on the topography of the immediate area and the distance to the top of slope, the estimated full length of the house was 25 metres with an approximate area of 170 m<sup>2</sup>. This house was oriented 95° east of north.

The average density of wall posts was 5.4 posts per metre, suggesting multiple repairs and a relatively long occupation (Figure 15). Walls were constructed using an offset post pair pattern except for the semi-circular east end where a single post row was found. There was a 1.6 metre wide opening in the east end for a doorway, and the east end was rounded. A row of posts was found crossing the interior of the house approximately three metres from the doorway. As in House 17, these posts may have been part of a structure to separate the rest of the house from the doorway. Several interior posts aligned in a row parallel to the side walls of the house were located in the middle area of the house along its central axis. The function of these posts is unclear, but their presence may be related to activities in the house rather than structural support. There was no post pattern within the house indicating the presence of a bunk line.

Eleven pit features and five support posts were excavated in this house. All the pit features were in the south half of the house while the support posts were in the north. This pattern is probably the result of the random placement of pit features in the house.

As was the case with House 18, House 19 was part of the early occupation phase of the site and was also one of the few houses that stood for the duration of the site (Figure 6).

## House 20

House 20 was one of the longest houses at the Mantle site (Figure 5). It was also one of the longest-occupied as it appears to have been used through the entire occupation of the site. The west end of the house extended beyond the modern development setback and limit of excavation, so its length was estimated. The exposed east portion of the house was 50.3 metres long and 7.9 metres wide enclosing an area of 369 m<sup>2</sup>, oriented at an angle of 96° east of north (Table 1). The estimated length of the house, with the location of the west end situated at the top of bank, would be approximately 54 metres covering a total area of 400 m<sup>2</sup>.

The house walls are predominantly made up of two patterns of posts (Figure 15). The offset post pair pattern was used to build the north and south walls, while single row posts were used to form the east end. The east end of the house was slightly rounded, but no doorway opening was observed, suggesting that the door was in the unexposed western portion of the house.

The parallel rows of posts that comprise the walls of House 20 suggest that these walls were rebuilt several times. The average wall post density is 7.9 posts per metre, which is the highest density observed in the Mantle village. The south wall was made up of two distinct rows of posts (three in one section) spaced 0.85 metres apart. The north wall appears to have been rebuilt two or three times with the inner north row placed 0.7 metres from the outer north row (Figure 15). The size of this house combined with the effort expended on rebuilding it and its location on the highest spot in the village suggest that this structure had an important and enduring significance in the community. The same can be said of nearby House 15, another very large, long-lived building.

Several interior posts within the house appear to have been related to activities within the house rather than for structural support. Near the centre of the house and along its central axis is a hearth with

associated posts from a cooking structure or rack. This hearth is located 20 metres from the east end. A concentration of posts in a roughly circular pattern was recorded in the west portion of the house (Figure 15). Feature 993 is the pit nearest to this concentration, and no hearth feature was found within these posts to suggest that this was a rack or cooking structure (Appendix B). It is possible that the circular post pattern seen here could have been an above ground sweat lodge. Some sites dating to this time period have structures within longhouses that are thought to have been above ground sweat lodges referred to as sweat baths (Finlayson 1985), and this post pattern in House 20 is similar to those. There is also another example of this circular pattern of interior posts in House 59, Feature 674 (see below).

Many features were found in this house, supporting the idea that it was used by a large number of people over a long period of time. Thirty-two pit features, seventeen support posts and one hearth were found in this house. There is a definite concentration of activity within the middle section of the house, with a high feature and wall post density (Figure 15).

As discussed earlier, House 20, along with Houses 15, 18 and 19, is one of the original structures on the site and was very likely occupied throughout the entire time that people were living in the village. Houses 20 and 15 may have served as a place for meetings of village council(s) and/or housed a prominent lineage in the community.

### **House 21**

House 21 was a small house adjacent to the east end of House 20 (Figure 5). Its length and width were 11.6 metres and 7.2 metres, respectively, making it the second shortest house at the site after House 42 (9.8 m) (Table 1). The enclosed area was 77 m<sup>2</sup> and oriented 96° east of north, the same as House 20, which might suggest that it was associated with the larger structure.

The walls and ends were composed of posts placed in a single row with a low average density of 2.7 posts per metre. The ends were rounded with a 1.5 metre wide opening in the east end that was probably used as a doorway (Figure 16). Houses 22 and 23 overlap this house, and since this small house was likely built around the time of House 20 in the early occupation phase, this house probably predated those other two houses (Figure 6). House 21 may have been an ancillary or special purpose structure related to House 20 that did not persist throughout the occupation of the latter structure. Due to the overlapping location of this house with two others, it is not possible to separate which features belong to which house. However, pit features 1391 and 1393 along with support post 1392 were found outside of the footprints of Houses 22 and 23, and were likely associated with House 21.

### **House 22**

House 22 was 28.0 metres long and 7.5 metres wide, covering an area of 199 m<sup>2</sup> (Table 1). It was located in the north half of the site in an area of earlier occupation phase houses (Figures 5 and 6). This house was oriented at an angle of 160° east of north, and this may have been done in order to make it fit within the space between Houses 20 and 27 (long-occupied early phase houses). House 22 postdates Houses 21 and 23, and was therefore part of the late occupation phase of the site (Figure 7).

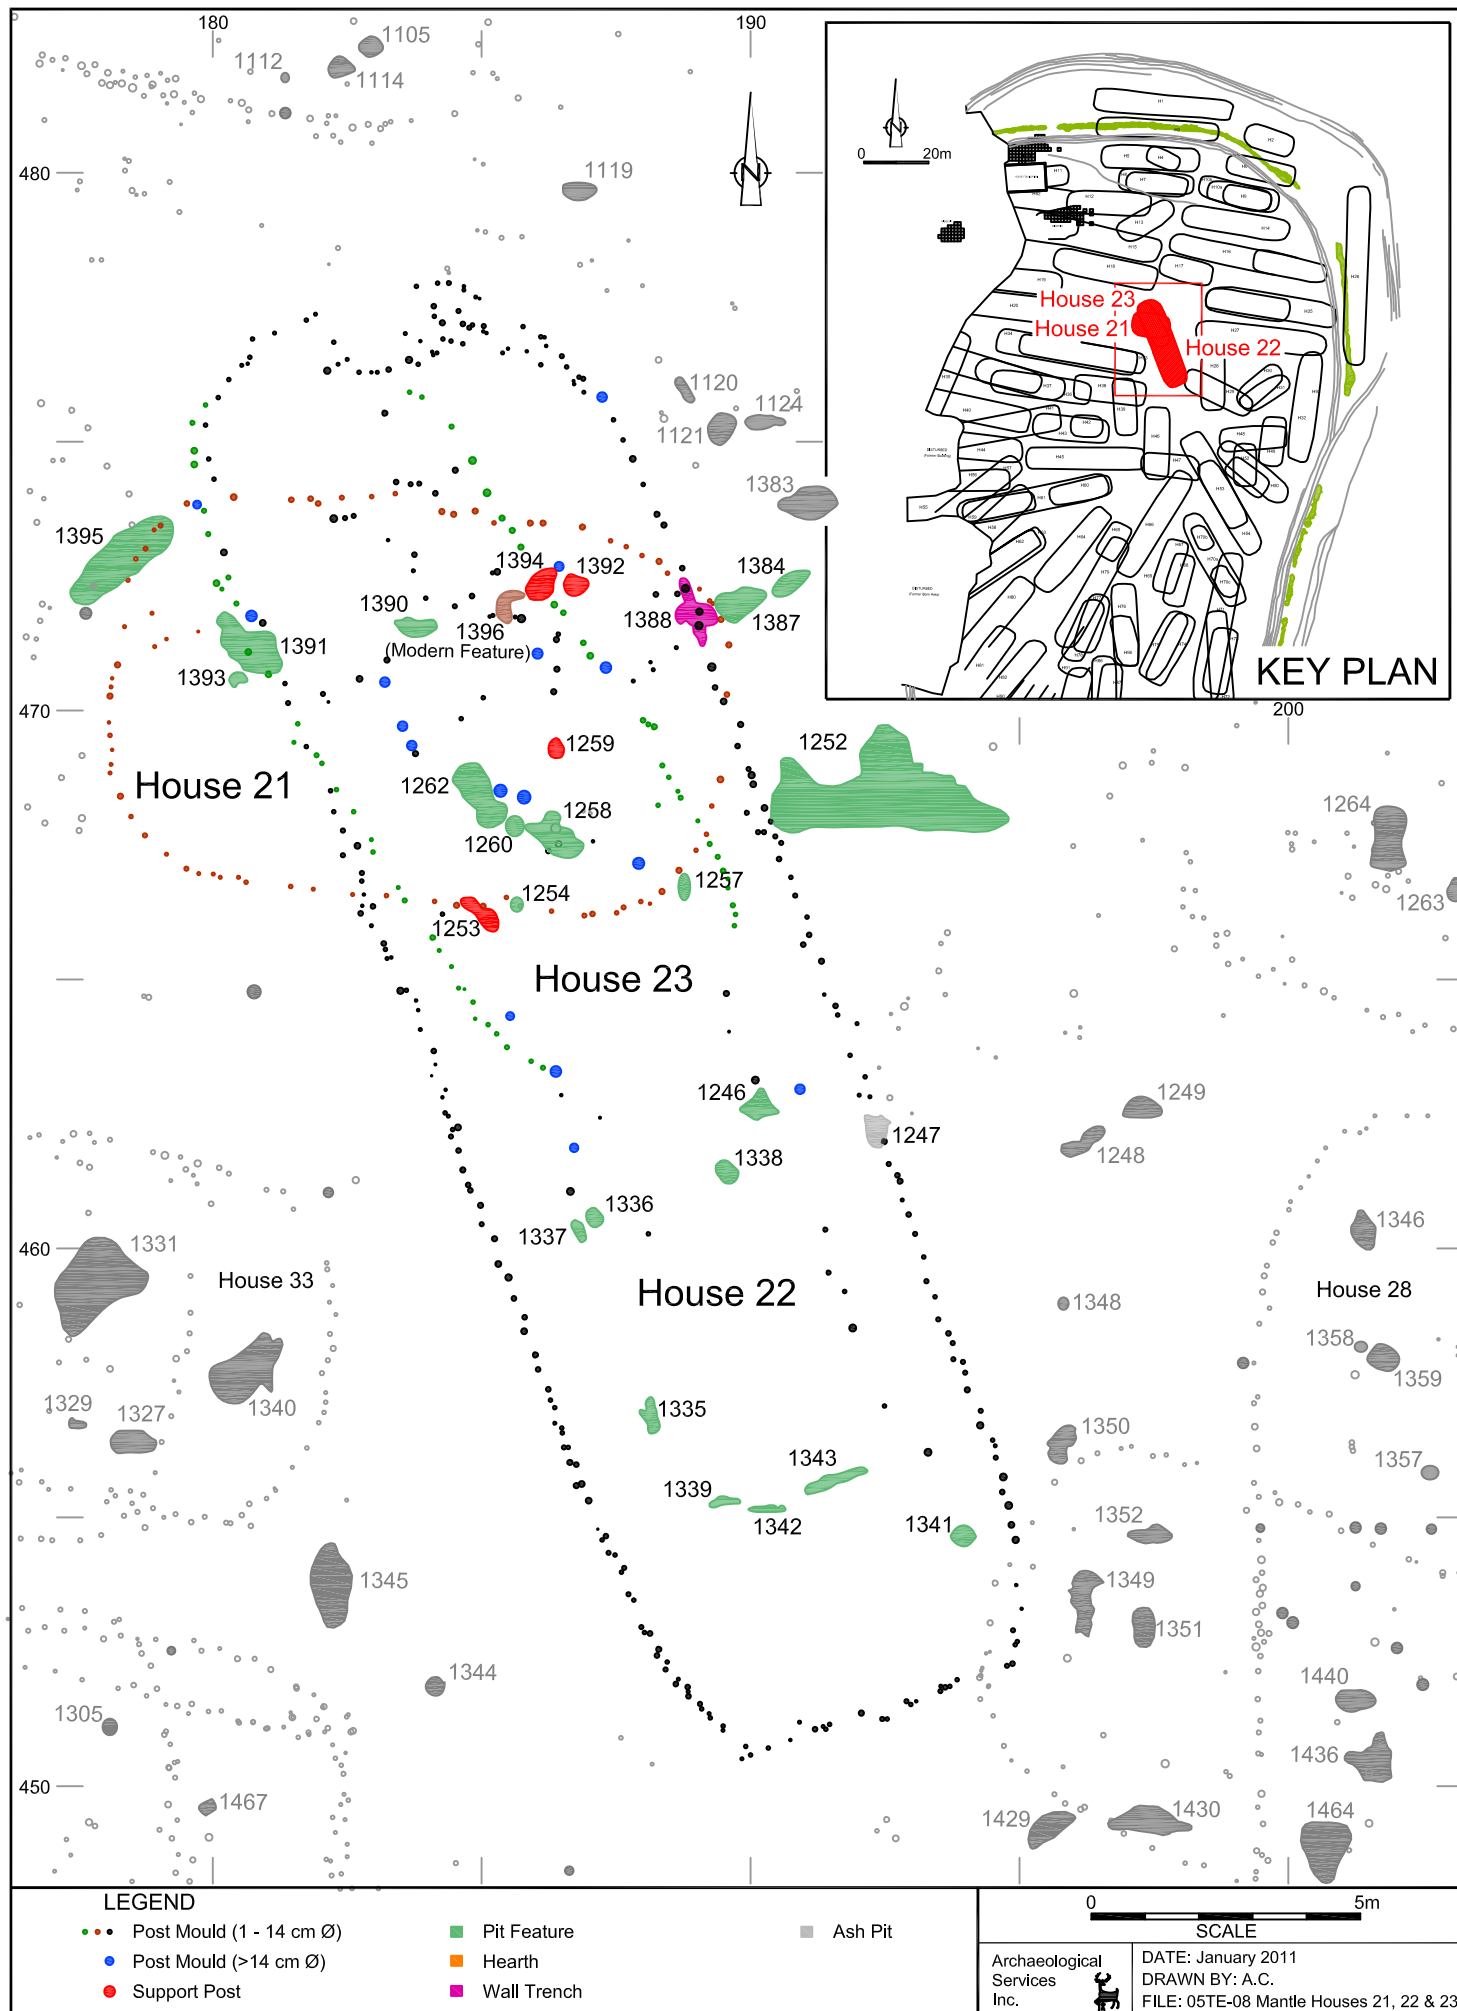

Figure 16: Plan View for House 21, 22 and 23

This house is one of three overlapping houses found within the same area. House 21 was first, followed by House 22 and then House 23. House 23 was a smaller structure found within the footprint of House 22 (Figure 16). There are a few features that were found in the area shared by both houses, but pit features 1246, 1335, 1336, 1337, 1338, 1339, 1341, 1342 and 1343 as well as ash pit feature 1247 were only within house 22 and should be considered to be contemporary with it.

The walls of this house were built mostly using posts placed in an offset pair pattern, but there were sections of single row posts. The average density of wall posts was 3.9 per metre. The plan shape of the north end was semi-circular with a 1.9 metre wide opening for a doorway located in the middle of the end. Posts forming a unique rectangular entranceway structure measuring 1.9 by 1.3 metres were located inside the house at the north end doorway (Figure 16). In contrast to the shape of the house's north end, the south end was squared off with no opening.

It would appear that House 21 was built first, perhaps serving as an ante-building to House 20. After it was removed, House 23 was built next, with House 22 built over it during the late phase of occupation.

### **House 23**

As discussed above, House 23 was in the middle of the sequence of construction involving Houses 21, 22 and 23 (Figure 16). It may have been constructed to replace House 21, but in a similar orientation to the terminal house in this location, House 22.

This house was contained within the footprint of House 22 and was superimposed over House 21 at an angle of 147° east of north (Figures 5 and 7). It was 14.2 metres long and 5.4 metres wide (Table 1) making it the narrowest house on the site. The walls were built using posts placed in a single row enclosing an area of 71 m<sup>2</sup>, with a low average density of 2.7 posts per metre. The ends of this house were not well defined, but it appears that both ends were rounded. Due to the overlapping arrangement of these three houses, it is impossible to definitively assign any features to this house.

### **House 24**

House 24 was located in the northeast area of the site between Houses 16 and 27 (Figure 5). It is almost entirely contained within the footprint of House 25 (Figure 14). The east end of House 25 overlapped the late phase palisade, so it should be considered to be an early phase house; therefore, House 24 belongs in the late phase (Figure 7). This house was 27 metres long, 7.5 metres wide, and enclosed an area of 199 m<sup>2</sup> at an angle of 101° east of north (Table 1).

The west end of the house did not have a clear single row of posts like most other houses, but instead had a clustering of posts in a semi-circular shape (Figure 14). The east end was more defined, with a shallow semi-circular shape and a 2.3 metre wide doorway opening in the middle. Posts in the south wall were placed in an offset pairing pattern, while the north wall had multiple rows of posts indicating a few repairs or re-building episodes along that wall. The average density of wall posts was 4.1 posts per metre.

House 24 was offset approximately one metre south of House 25 and two metres west. Twenty-four pit features and fourteen support posts were contained in this house. Due to the large overlapping area between these two houses it is unclear what features were associated with which house. Only two of the pit features and one support post were found outside of House 25 but within House 24 (Figure 14). It is possible that House 24 was built to replace the longer House 25 when the palisade was contracted.

## House 25

House 25 was the earlier house located in the same place as House 24 (Figure 5). The east end of this house overlaps four rows of posts in the late phase palisade and therefore pre-dates that palisade.

This house was 40.3 metres long and 7.6 metres wide (Table 1). It covered an area of 298 m<sup>2</sup> and was oriented 99° east of north. The walls were composed of pairs of posts while the ends were made up of a single row of posts (Figure 14). The north wall was composed of pairs of posts with some being offset while the south wall had either a single row or clustering of posts. The average wall post density was 2.7 posts per metre, which suggests a short occupation. The west end of the house was squared off, and the east end was rounded. There was a 2.1 metre wide gap in the east end for a doorway and no doorway opening was apparent in the west end. The 4.5 metre wide opening located in the middle section of the south wall may have been for a doorway, but evidence of posts within this opening could have been lost by the construction and occupation of the late phase House 24.

As discussed above, most of the features contained within these two houses were located in an overlapping area. However, four pit features found near the east end are only within the boundaries of House 25. This house was part of the early occupation phase group in the north half of the site (Figure 6).

## House 26

House 26 was a long, isolated house located completely outside of the inner, late phase palisade (Figure 5). The borrow trench midden (Feature 55) crossed over the west wall and south end of the house. Since Feature 55 is contemporary with the late phase palisade and would not have existed at the same time as this house, it can be concluded that House 26 was part of the early occupation phase of the site (Figure 6).

This house was 6.8 metres wide and 55.5 metres long, making it the longest structure at the site (Table 1). It was oriented 2° east of north and enclosed an area of 363 m<sup>2</sup>, with an average density of wall posts of 3.8 posts per metre. The walls were made up of a single row of posts with no interior post pattern to suggest internal framing or a bunk line (Figure 17). The ends were semi-circular in shape with a 3.2 metre wide doorway opening found in the north end. Another opening 3.5 metres wide was found in the east wall in the south half of the house.

There were no pit features found within this house with the exception of Feature 42, a small pit located on the line of posts forming the south end of the house. The absence of features and hearths suggest that this house was not occupied year round or for very long. Since it was part of the early occupation phase, this house could have been built to house people involved with the initial construction of the village.

Assuming that construction would take place spring to fall when the ground is not frozen, it is likely that the cooking of food would have taken place outside the house. This is supported by the presence of a large hearth (Feature 41) found five metres east of the south end of the house (Figures 17).

## House 27

House 27 was located 2.5 metres south of House 25 in the northeast area of the site (Figure 5). Since its orientation is parallel to other early phase houses in this area of the site, and since it appears to have been built in two stages (see below), it is probable that this house was built during the early phase of occupation (Figure 6). However, this house was expanded once so it likely stood through the middle and into the late phase as well.

The first version of House 27 was 17.1 metres long and 7.6 metres wide covering an area of 117 m<sup>2</sup> (Table 1). Walls were made up of posts placed in a single row with a clustering of posts where the north

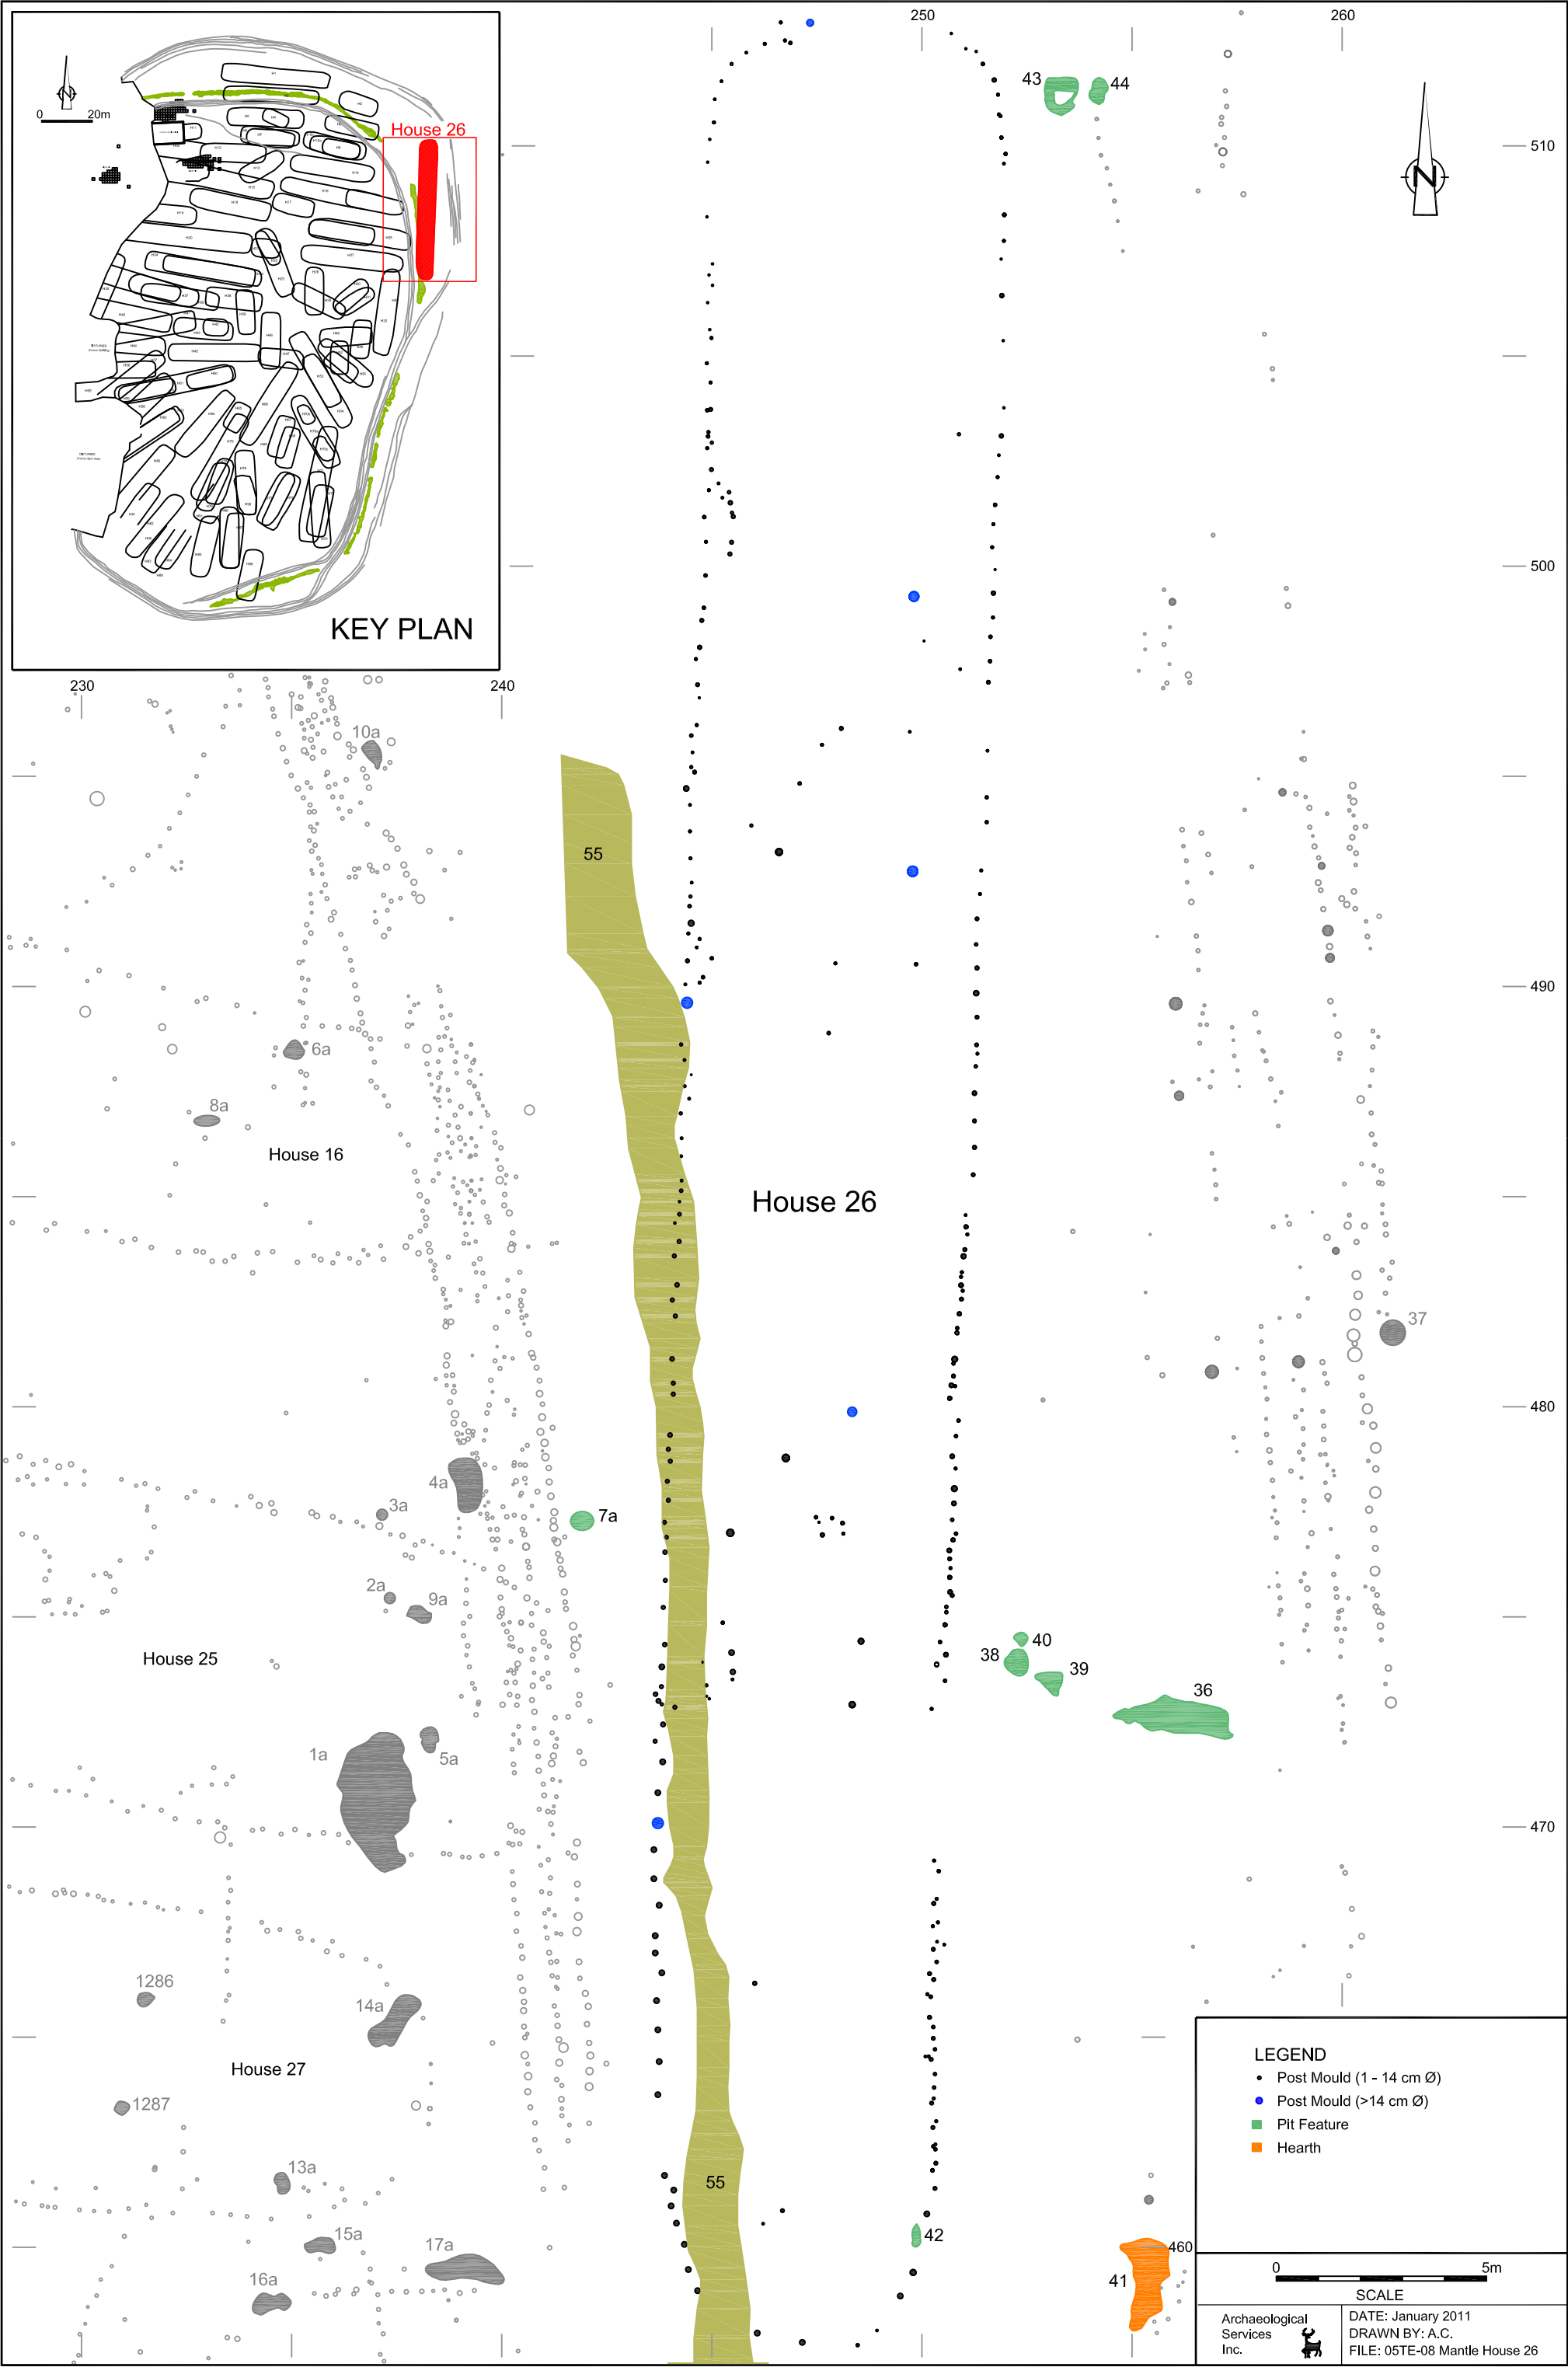

Figure 17: Plan View of House 26

and south walls were extended to the west (Figure 18). The average density of wall posts was 4.1 posts per metre. The east end was rounded in plan view with a 1.5 metre wide doorway opening located on the south side of the central axis of the end. The row of posts that crossed over the middle section of the house was the original west end of the house. It had a flatter shape than the east end and appeared to be almost concave. Posts used to form this end were placed very close together with no gap to indicate the presence of a doorway.

Later, House 27 was extended west 23.3 metres to a maximum length of 40.4 metres, but the width remained the same. The total house area was 286 m<sup>2</sup> and it was oriented 96° east of north (Table 1). The single row of wall posts established during the initial construction of the house was continued into the extension with some additional posts placed in the south wall (possibly for structural strengthening). The west end was a similar shape to the east end with a 2.5 metre doorway opening in the centre. Although several interior posts were found within the house, none formed a pattern indicative of a bunk line. Instead, they were more randomly placed and may have been related to household activities.

Pit features were evenly distributed within the house with seven located in the early phase of the house and twelve found in the larger western extension. A total of seven support posts was identified: three in the later section and four in the earlier house.

House 27 was occupied during the early and later phases of the village. It was situated close to the open area on the east side of the site and was part of the north group of houses oriented perpendicular to the top of the east bank of Stouffville creek. As the village evolved over time, a more random pattern of house placement and orientation was utilized, and new structures such as Houses 22, 28, 32, and 30/31 were built around this one (Figure 7).

## **House 28**

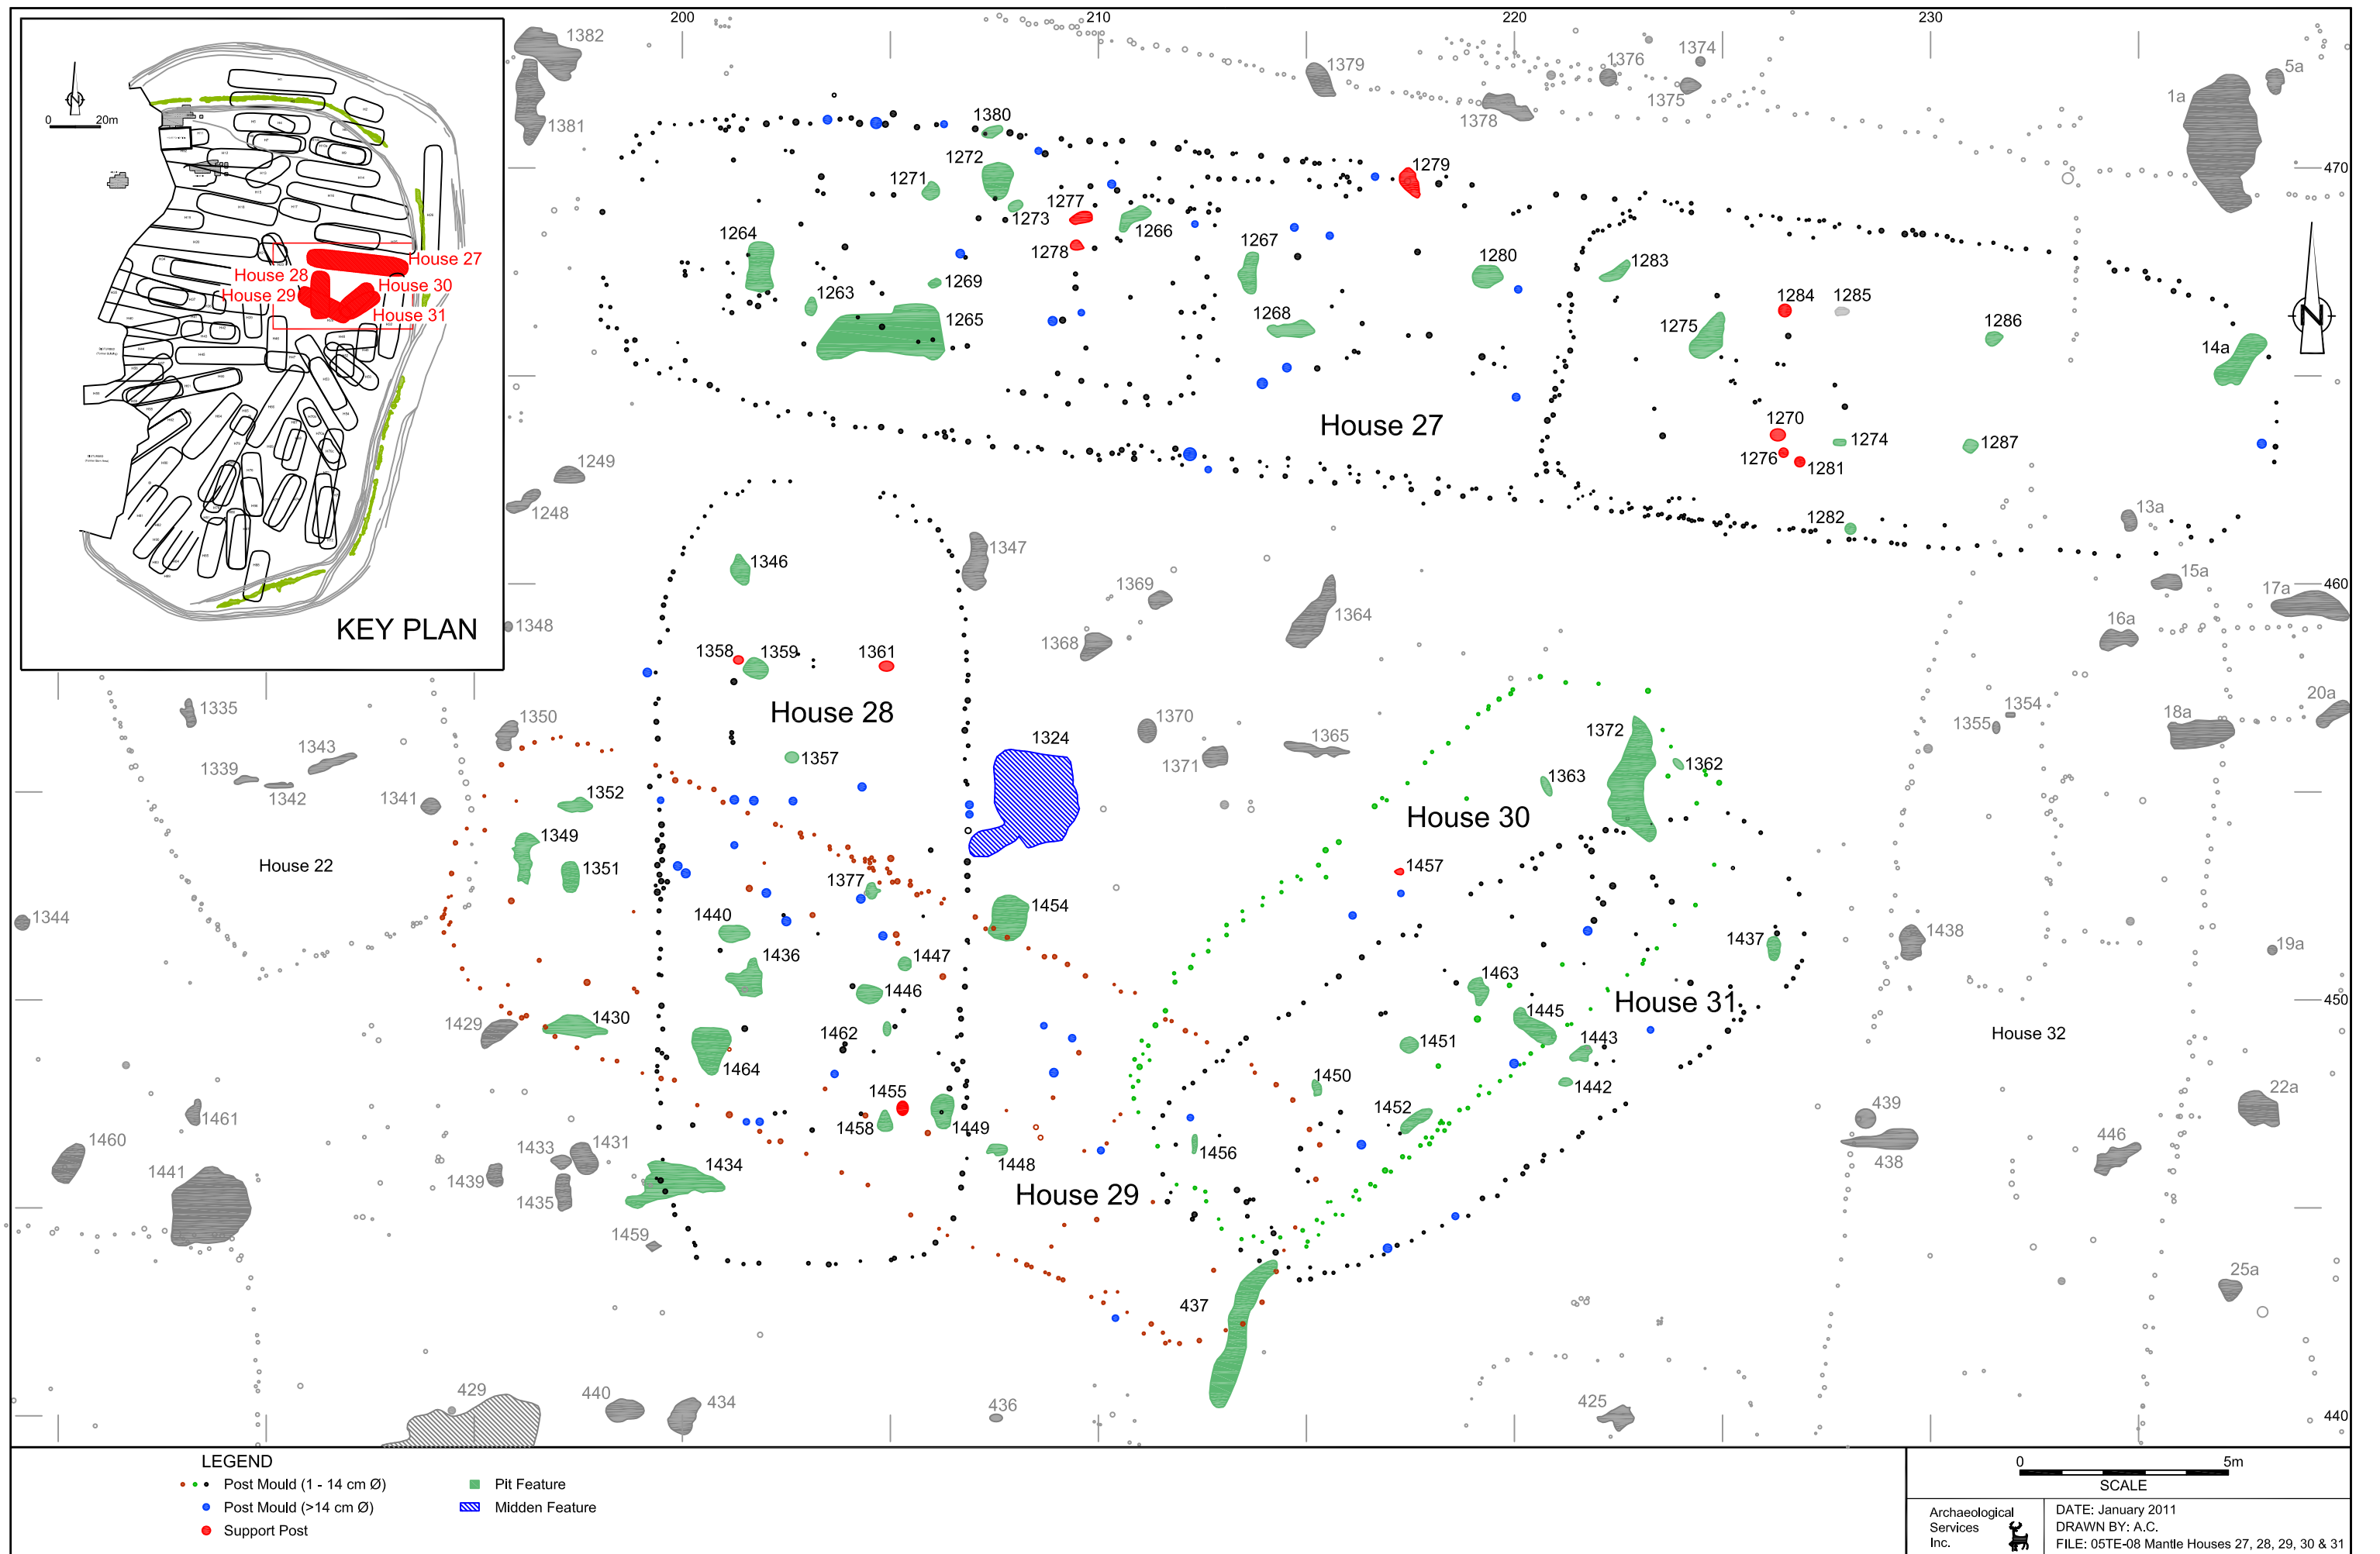

House 28 measured 18.8 metres long and 7.5 metres wide, and was oriented 0° north enclosing an area of 130 m<sup>2</sup> (Table 1 and Figure 5). This house overlapped House 29, which probably belonged to the early phase of occupation, and is located 1.6 metres south of House 27. House 29 was built in the early phase because it overlapped the area of House 22, which was constructed in the late phase. Therefore, House 28 was built after House 29 was deconstructed, and must be part of the late occupation phase of the site (Figure 7).

The walls and ends were built by placing posts in a single row, with an average density of 3.1 posts per metre (Table 1). The east and west sides at the north end were slightly tapered, and the end was rounded. The side walls at the south end were rounded with a squared off end. A 1.6 metre wide doorway located in the middle of the north end was the only opening leading into the house (Figure 18). It is not possible to establish which features found in the overlapping area of Houses 28 and 29 belong to which house. However, features in the north portion of the house clearly belong to House 28. Three pit features and two support posts were contained in this portion. A small midden-like feature (Feature 1324) was found adjacent to the outside of the east wall that may have been associated with this house (Appendix B).

House 28 appears to be part of a group of four houses (28, 29, 30, and 31) located on the east side of the site (Figure 6). The overlapping positions of these houses suggest that three construction events took place, with House 28 being part of the final one. This group of houses is situated to the north of, or possibly in the northern area of, the proposed plaza in the east-central portion of the site. It may have been that this group of four houses was temporary or short-lived owing to this proximity, and may have been used to house temporary visitors to the site or constructed on an ad-hoc basis as the need for more roofed space increased (see also the discussion of Houses 48, 49, 50, 51, and 52 below).

**House 29**

As described above, House 29 was an early phase house within the four house group that included Houses 28, 29, 30 and 31 (Figure 5). This structure was located 8.8 metres south of House 27 and nine metres east of House 38 (Figure 5). It measured 22.1 metres long and 6.9 metres wide. It was oriented 116° east of north and enclosed an area of 142 m<sup>2</sup> (Table 1).

The house walls and ends were constructed using a single row of posts with an average density of 3.3 posts per metre. The cluster of posts in the middle of the north side wall might be evidence of a repair to the wall (Figure 18). Both ends of the house were slightly curved in shape, and no obvious doorway opening was seen at either end or in the sides of the house.

It is not possible to determine which features found in the overlapping area of Houses 28 and 29 belong to which house. Pit features 1349, 1351, 1352 and 1430 in the northwest portion and pit feature 1448 in the southeast portion were only within the boundaries of House 29, and were therefore associated with this house (Figure 18 and Appendix B).

**House 30**

House 30 was small structure that measured 16 metres long and 6.8 metres wide, enclosing an area of 109 m<sup>2</sup> and oriented 50° east of north (Table 1). This house overlapped House 31 with fifty-two percent of its area sharing the same space as House 31 (Figure 5). The houses were similar in size, with House 30 oriented 8° more to the north.

The house walls were constructed using posts placed in pairs in an offset pattern; this is most obvious in the northwest wall towards the south end (Figure 18). Other sections of the side walls and the ends had a single row of posts, resulting in an average density of 4.3 posts per metre. The side walls were slightly tapered, forming rounded ends. There was no clear doorway opening, but a two metre wide gap in the south end (with only a single post in the centre of that gap) could be interpreted as a doorway.

Since this house shared the same location as House 31, the two could not have existed at the same time. Many of the features found in these houses were located in the area common to both structures. Three pit features and one support post were located outside of House 31 but within House 30. Therefore, features 1362, 1363 and 1372 as well as support post 1457 would have been associated with House 30 (Figure 18).

House 30 postdates House 29 and could have been contemporary with House 28, but it must have existed at a different time than House 31 (Figure 7).

**House 31**

House 31 was located in the same place as House 30, and sixty percent of the area of this house overlapped with House 30 (Figure 5). It was 16.4 metres long and 6.4 metres wide covering an area of 92 m<sup>2</sup>, and was slightly smaller than House 30 (Table 1). This house was oriented 58° east of north.

A single row of posts was used to construct the walls and ends of this house, with a low total wall post density of 2.7 posts per metre. The house shape was similar to House 30 except that two doorway openings were found in the side walls of House 31: a 1.4 metre wide opening in the north-west wall and a 1.5 metre wide opening in the southeast wall (Figure 18).

Aside from the features found in the overlapping area between the two houses, three pit features were located outside of House 30 but inside House 31. Features 1437, 1442 and 1443 should be considered contemporary with House 31.

The overlapping location and similar size of Houses 30 and 31 suggest that one was built to replace the other. It cannot be determined with any certainty which house was built first, but it is likely that these houses were both part of the middle to late occupation of the site (Figure 7). For reasons outlined earlier, House 29 was assigned to the early phase and House 28 part of the late phase. Houses 30 and 31 could have been contemporary with House 28 but not with each other. Therefore the chronological sequence of construction of these four houses was as follows: House 29; then House 30 or 31; and finally House 28.

## **House 32**

House 32 was located on the east side of the site, 4.2 metres inside of the late phase palisade (Figure 5). It measured 34.2 metres long and 7.7 metres wide enclosing an area of 241 m<sup>2</sup> (Table 1). It was oriented 6° east of north with the north end of the house partially overlapping the south wall of House 27 (a long standing early occupation phase house). House 32 likely postdates House 27 and was part of the late occupation phase of the village (Figure 7).

The wall posts of this house were mainly placed in a single row; however, there are some sections of the walls where the posts were paired and offset from each other (Figure 19). The total average wall post density was low (2.7 posts per metre), which is perhaps indicative of a short occupation. Very few interior posts were present with no indication of framing or a bunk line. The north end was semi-circular in plan view with a 2.5 metre wide doorway opening in the middle, while the south end was squared off. No doorway opening was found in the south end of the house.

House 93 was a small structure that partially overlapped House 32 (Figure 19). Eight pit features, one support post and one ash pit were contained within House 32. Two of those pit features (Features 18a and 446) were in the area overlapping House 93, and therefore cannot be directly associated with either of these houses. Feature 13a was found in the area where the north end of House 32 overlaps House 27 and could be associated with either house (Appendix B).

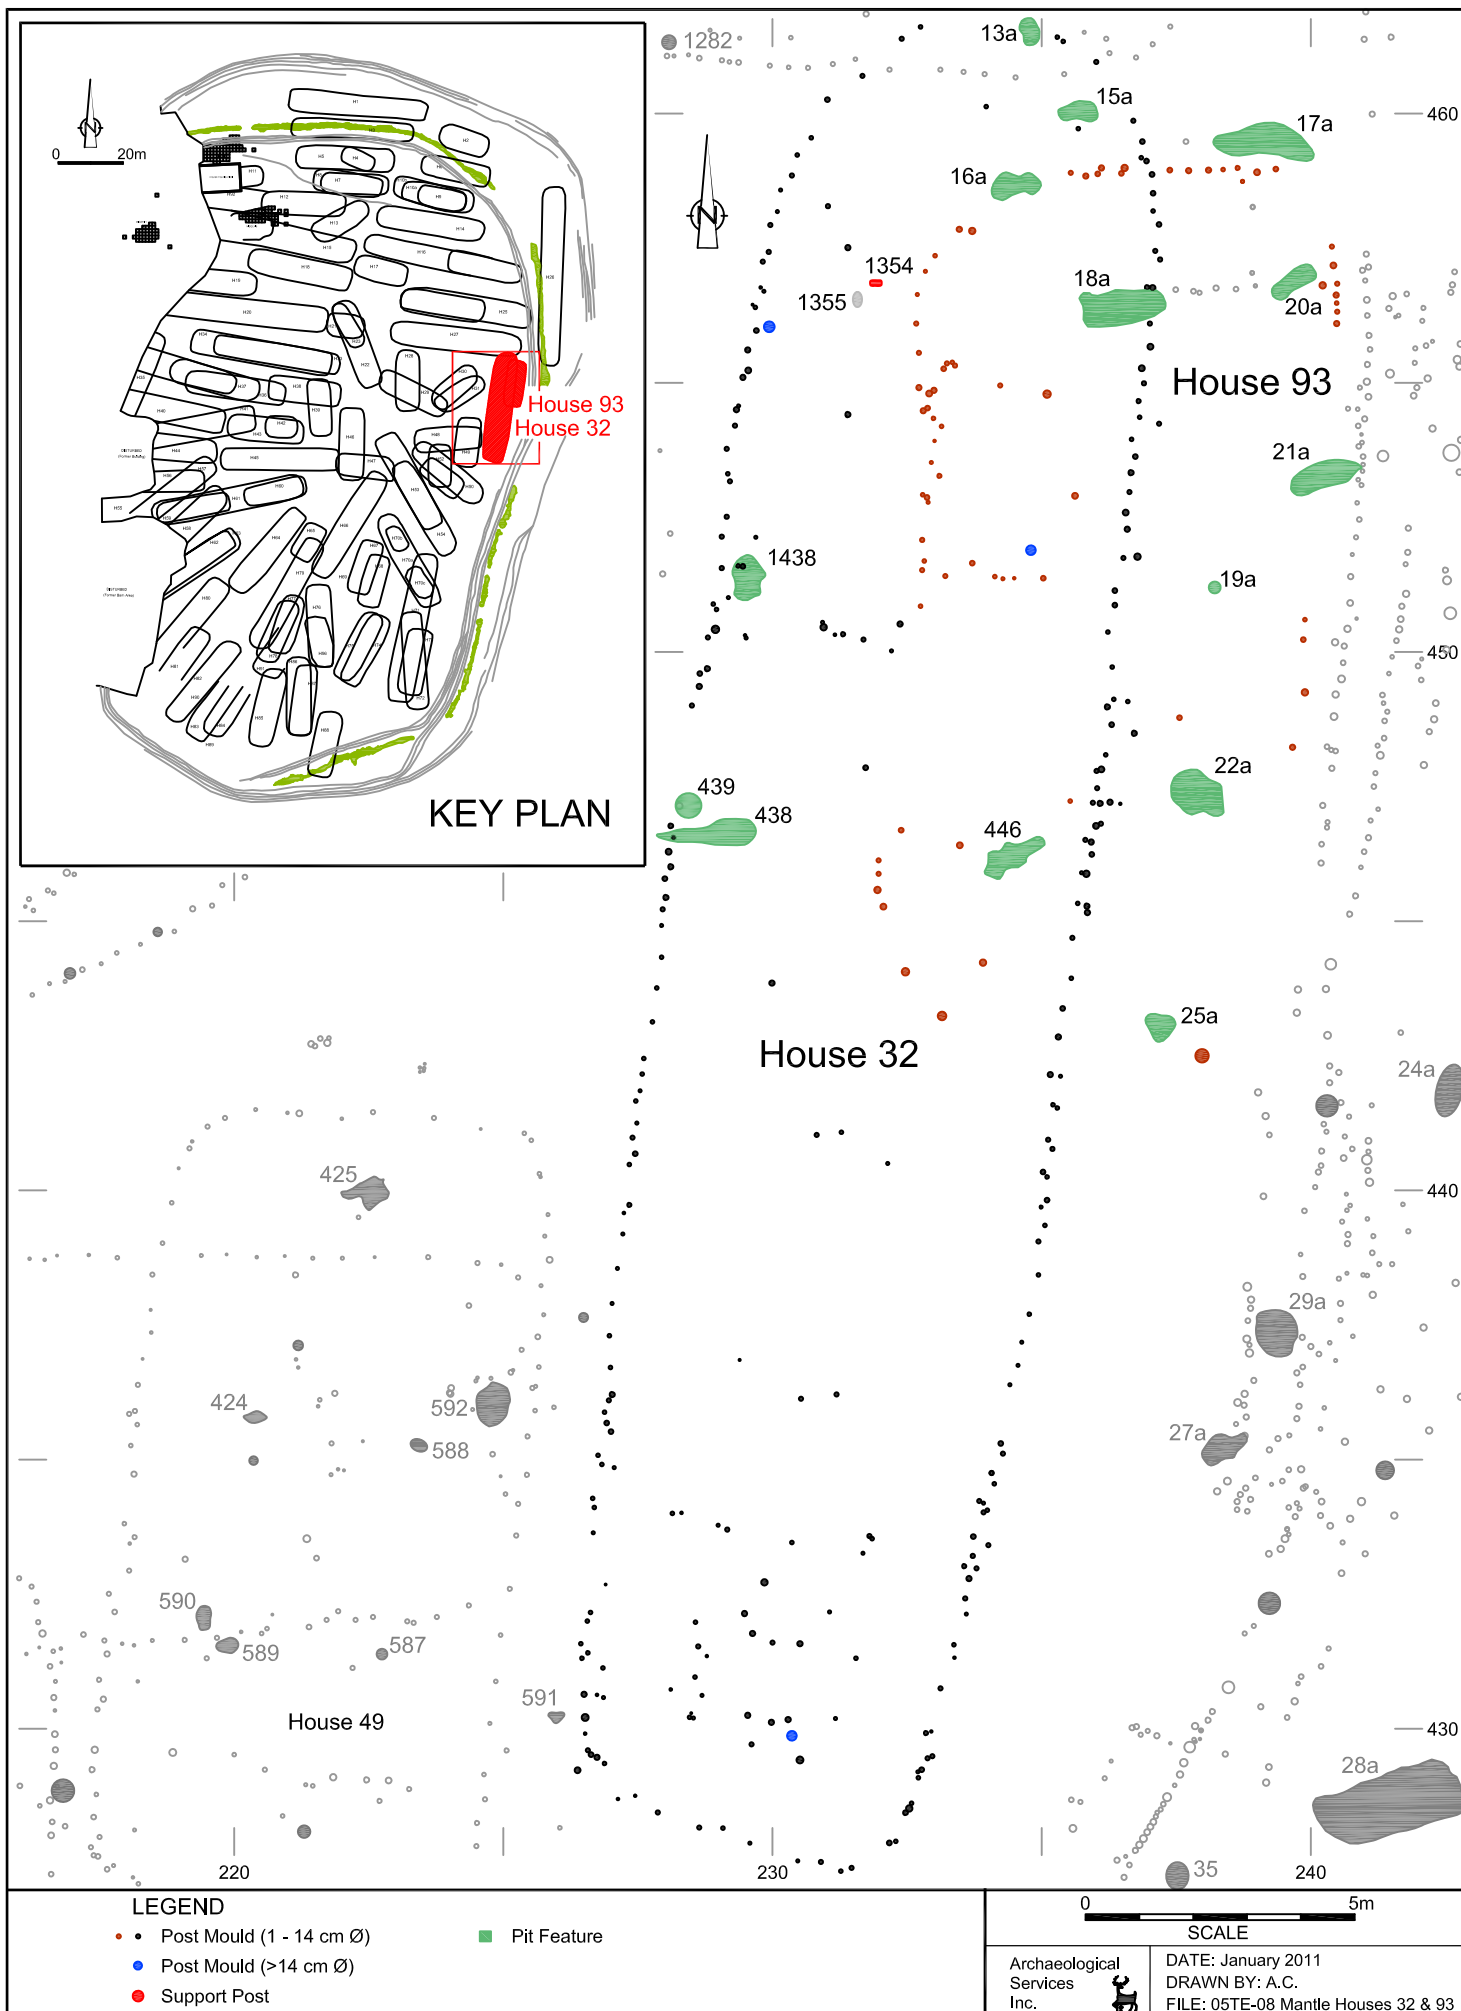

Figure 19: Plan View of Houses 32 and 93

## **Houses 33 and 34**

These houses directly overlapped each other with one of them part of the early phase of occupation and the other in the late phase (Figure 5). Their orientation angles are virtually the same with House 33 at 99° east of north and House 34 at 100° east of north.

House 33 measured 39.2 metres long and 6.5 metres wide and covered an area of 244 m<sup>2</sup> (Table 1). House 34 was 43.2 metres long and 7.7 metres wide enclosing 329 m<sup>2</sup>. The post patterns for the house walls are both single row and offset pairs. The walls of House 33, the smaller house, were mainly composed of posts placed in a single row with the exception of the west end of the north wall where some post pair was found. The average wall post density of House 33 was low, 2.6 posts per metre. House 34 had mostly paired and offset posts, except for parts of the south wall where a single row of posts was found. The wall post density of House 34 was 3.8 posts per metre, suggesting that this house was occupied longer than House 33 (Figure 20).

The east end of House 33 was curved in shape and was formed by a single row of posts while the western house ends were flatter in plan view. There were two openings, 1.6 and 2.4 metres wide, respectively, in the north walls of both houses that likely functioned as doorways (Figure 20). These doorways were situated in the same place in both houses possibly, which suggests that little time passed between the destruction of one house and the construction of the other. A third opening 1.5 metres wide was also found in the north wall of House 34.

House 34 was probably the later and longer occupied house of the two (Figure 7). There appears to have been three west ends of the house, indicating that this house was subject to three expansion events. After House 33 was removed (Figure 6), House 34 was built to an initial length of 39 metres with an area of 290 m<sup>2</sup> (Table 1). It was then lengthened an additional 2.8 metres (expanded area of 313 m<sup>2</sup>), and finally another 1.4 metres was added to the house for a final length of 43.2 metres. House 34 has a tighter placement of posts in the walls than House 33, which would result in a stronger and more enduring structure.

Many features and posts were found within these houses suggesting a long occupation of the house area. Due to the parallel overlapping alignment of these two houses it is not possible to attribute any feature with either house. There is a small midden-like feature (Feature 1250) adjacent to the north walls of the houses. There was evidence that some posts from the north wall of House 34 were set in the fill of Feature 1250 therefore postdating the feature. This feature abutted but did not overlap the north wall of House 33, so they are likely contemporary (Appendix B).

It cannot be determined when House 33 was dismantled and House 34 was built, but, along with Houses 15, 18, 19 and 20, they were part of the original structures oriented perpendicular to the creek bank that stood for most of the time that the village was occupied.

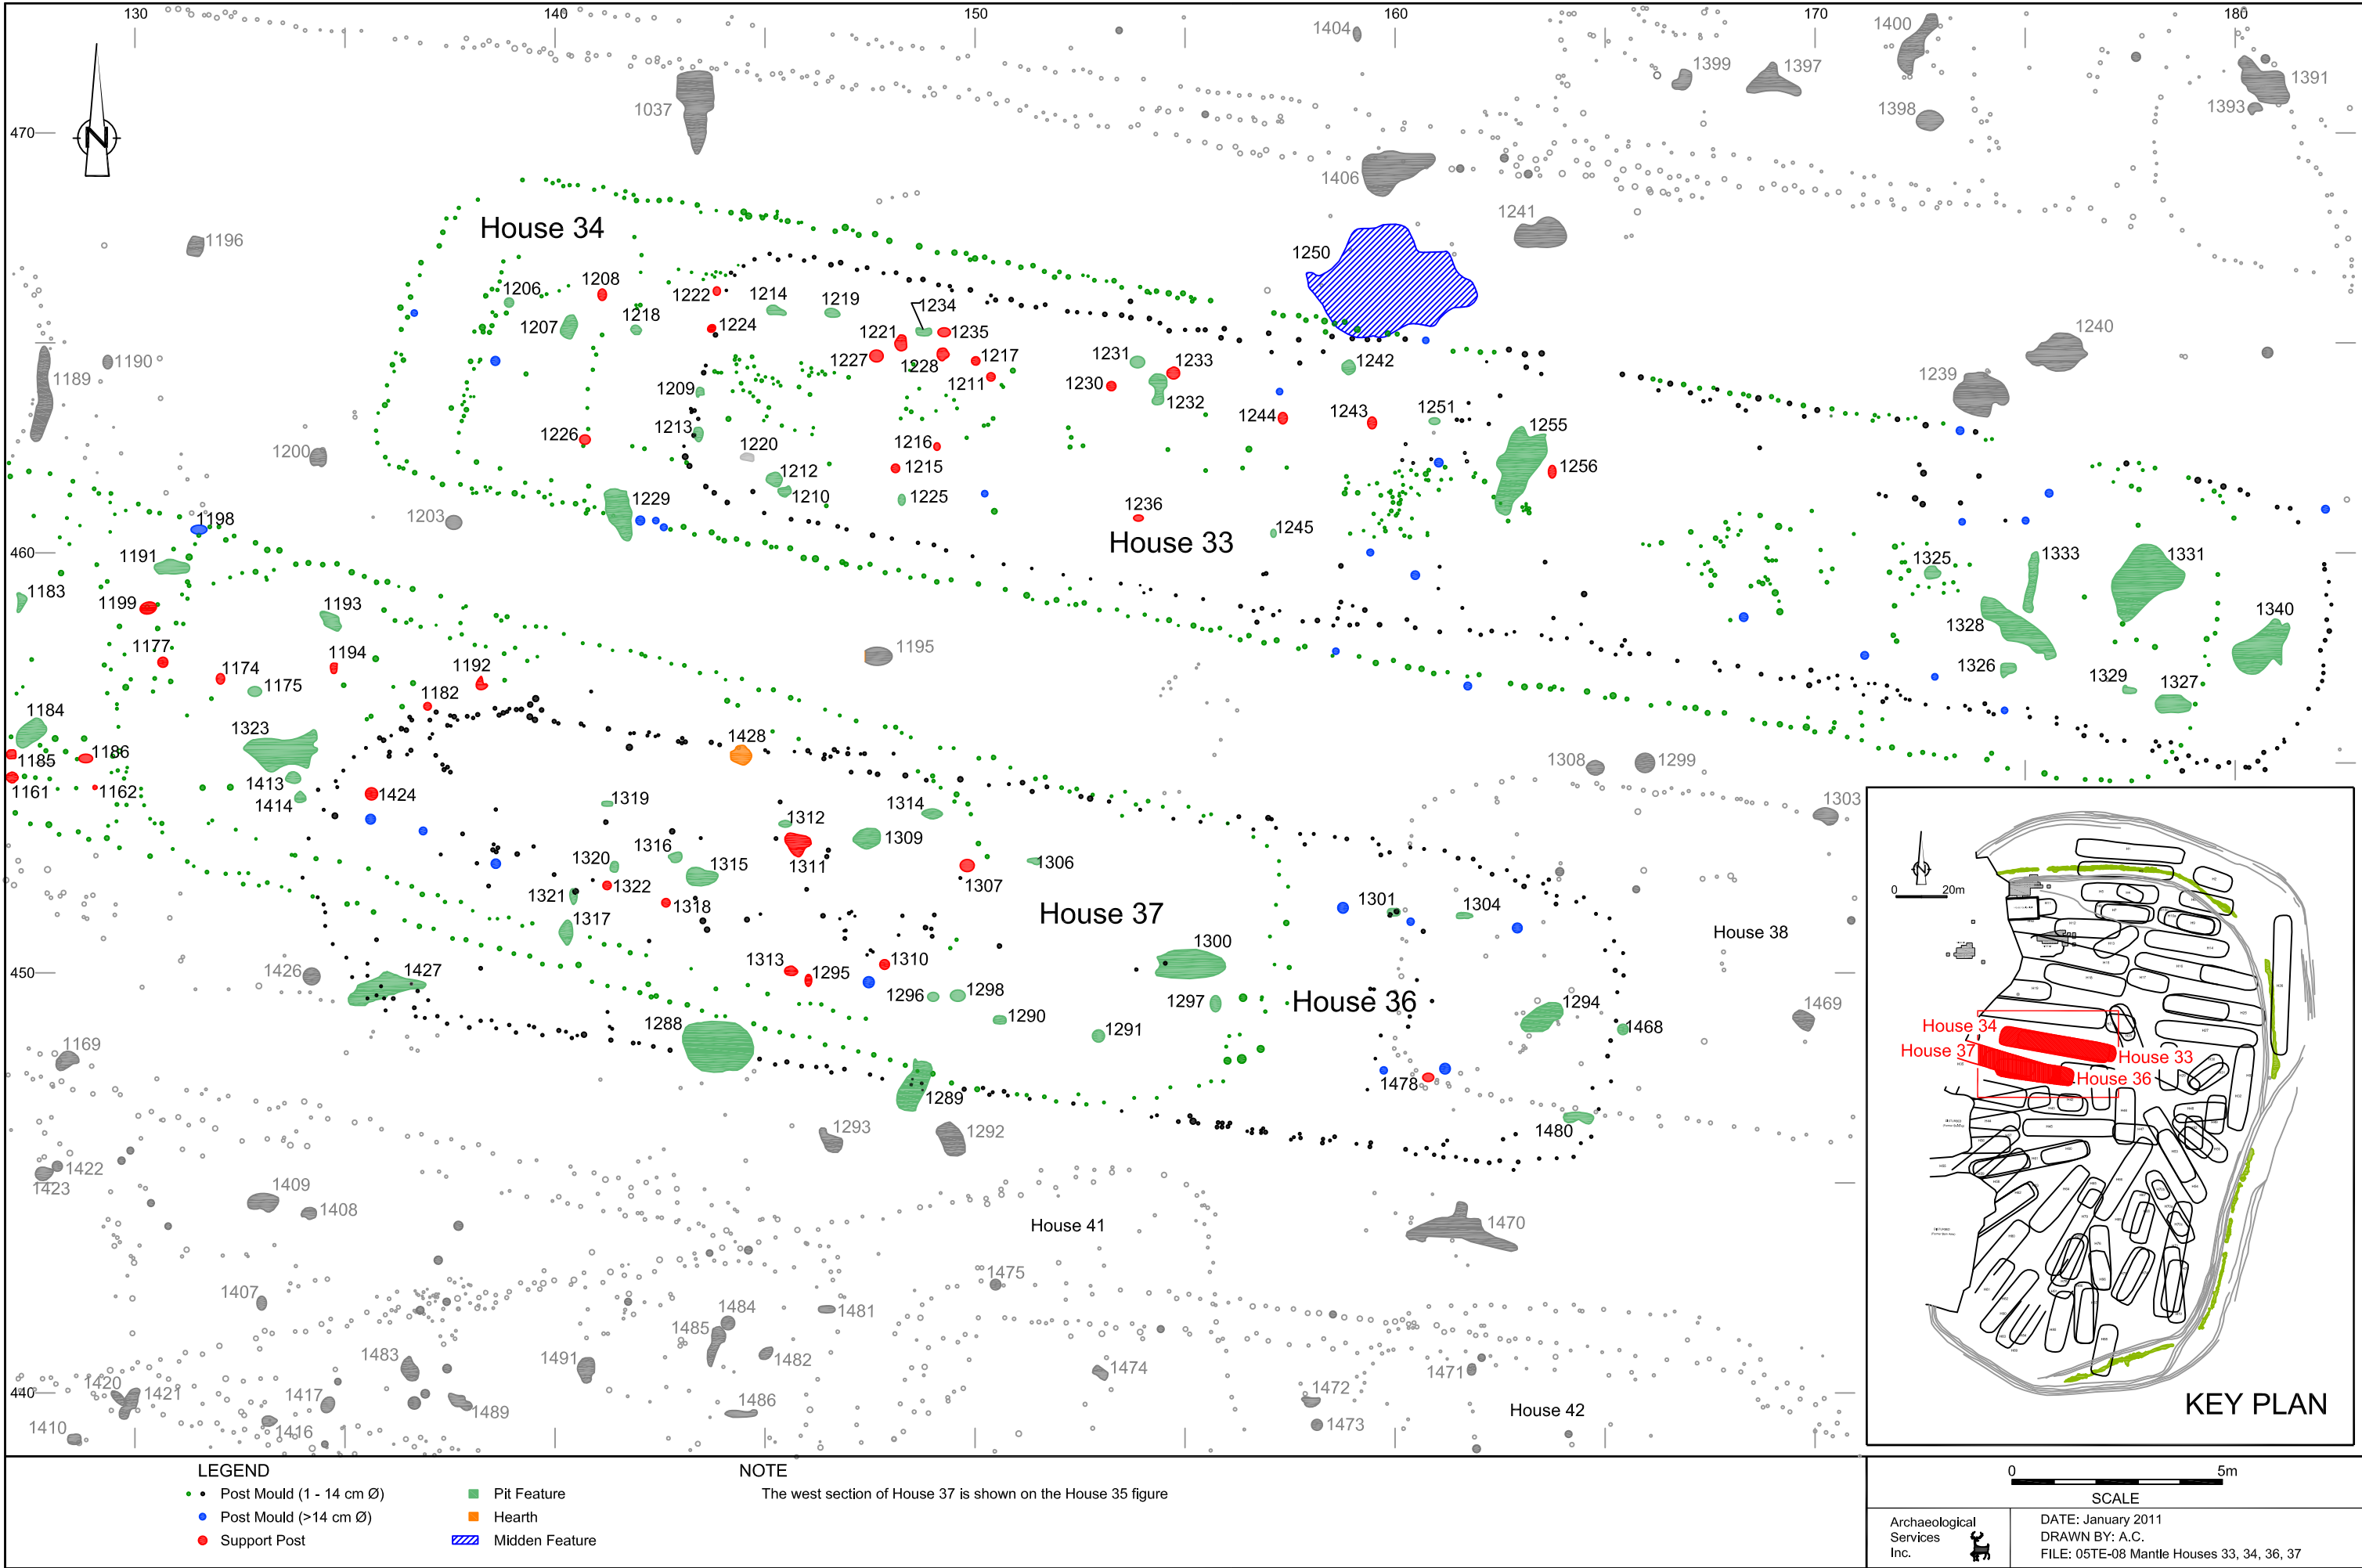

Figure 20: Plan View of Houses 33, 34, 36 and 37

### House 35

This house was located parallel to the top of the creek bank on the west side of the site (Figure 5). Assuming that the posts found below Midden 1 are part of the west palisade that was built along the top of the bank and parallel to the slope, then the west wall of this house would have been within five metres of that palisade. This west wall was beyond the development setback and limit of excavation, so it was not exposed. The south end of the house had been previously disturbed by the construction of a farm building, so it was not possible to accurately measure the length of this house. An estimated length was calculated based on its proximity to contemporary houses and minimum spacing between those houses.

The exposed length of House 35 was 26.3 metres with a minimum width of 5.8 metres (Table 1). It was oriented 23° east of north with an exposed area of 132 m<sup>2</sup>. This house overlapped House 37, which was occupied in the early phase (see below), so House 35 must date to a later time (Figure 7). House 41 was also probably occupied during the late phase (see below). Given the orientation of House 41, the alignment of its north wall could be extended to meet the alignment of the east wall of House 35. The maximum length of House 35 was estimated to be 30 metres, and the estimated width was 7.2 metres, similar to other houses occupied during the late phase (Table 1). The maximum area of House 35 using the estimated length and width would have been 208 m<sup>2</sup>.

The posts used to construct the east wall of House 35 were placed in both pairs and a single row, with a total wall post density of 4.0 posts per metre. The middle section of the wall showed a thickening with more posts used. This could have been the result of wall repair or strengthening. The north end of the house is semi-circular in shape with pairs of posts used rather than a single row as seen on many of the other houses in the village. No opening for a doorway was evident in the exposed wall and end of the house (Figure 21).

Several features were contained within this house as well as the areas overlapping Houses 37 and 40. Seven pit features and two support posts were found in the house, but only three pit features (Features 1188, 1189 and 1238) as well as support post 1237 were located in parts of the house not shared by House 37 or 40 (Figure 21 and Appendix B).

### House 36

House 36 was situated on the west side of the site in the central area (Figure 5). It directly overlapped House 37 and was located 4.4 metres south of House 34 and 1.3 metres north of House 41 (Figure 20).

House 36 was 31.0 metres long and 7.4 metres wide. It was oriented 98° east of north and covered an area of 217 m<sup>2</sup> (Table 1). The posts used to construct the walls were placed in pairs with some of the posts offset from each other. The average density was 4.1 posts per metre. There was a clustering of posts along the south wall, which could have been done to strengthen it when the wall was extended to lengthen the house in the west end. The west end and both east ends were semi-circular in plan view, with the central area of the second end slightly flattened. There was no obvious opening for a doorway in the walls or ends; however, a 1.9 metre wide gap in the south half of the west end, with only two posts in that space, may have served as a point of entry (Figure 20).

There were several pit features and support posts as well as a hearth contained in this house (Appendix B). Most of them were found in the area overlapping Houses 37 and 94, so it becomes difficult to associate these features with a particular house. There are some exceptions, such as the hearth near the north wall of House 36, suggesting that this hearth did not belong to House 36 but instead belonged to House 37 (Figure 20). Three pit features were found overlapping the alignment of the south wall. Features 1289 and 1427 likely predate House 36 because the posts could be seen in the fill of the feature. No posts were found within or below Feature 1288, so either the south wall posts were not set very deep in the

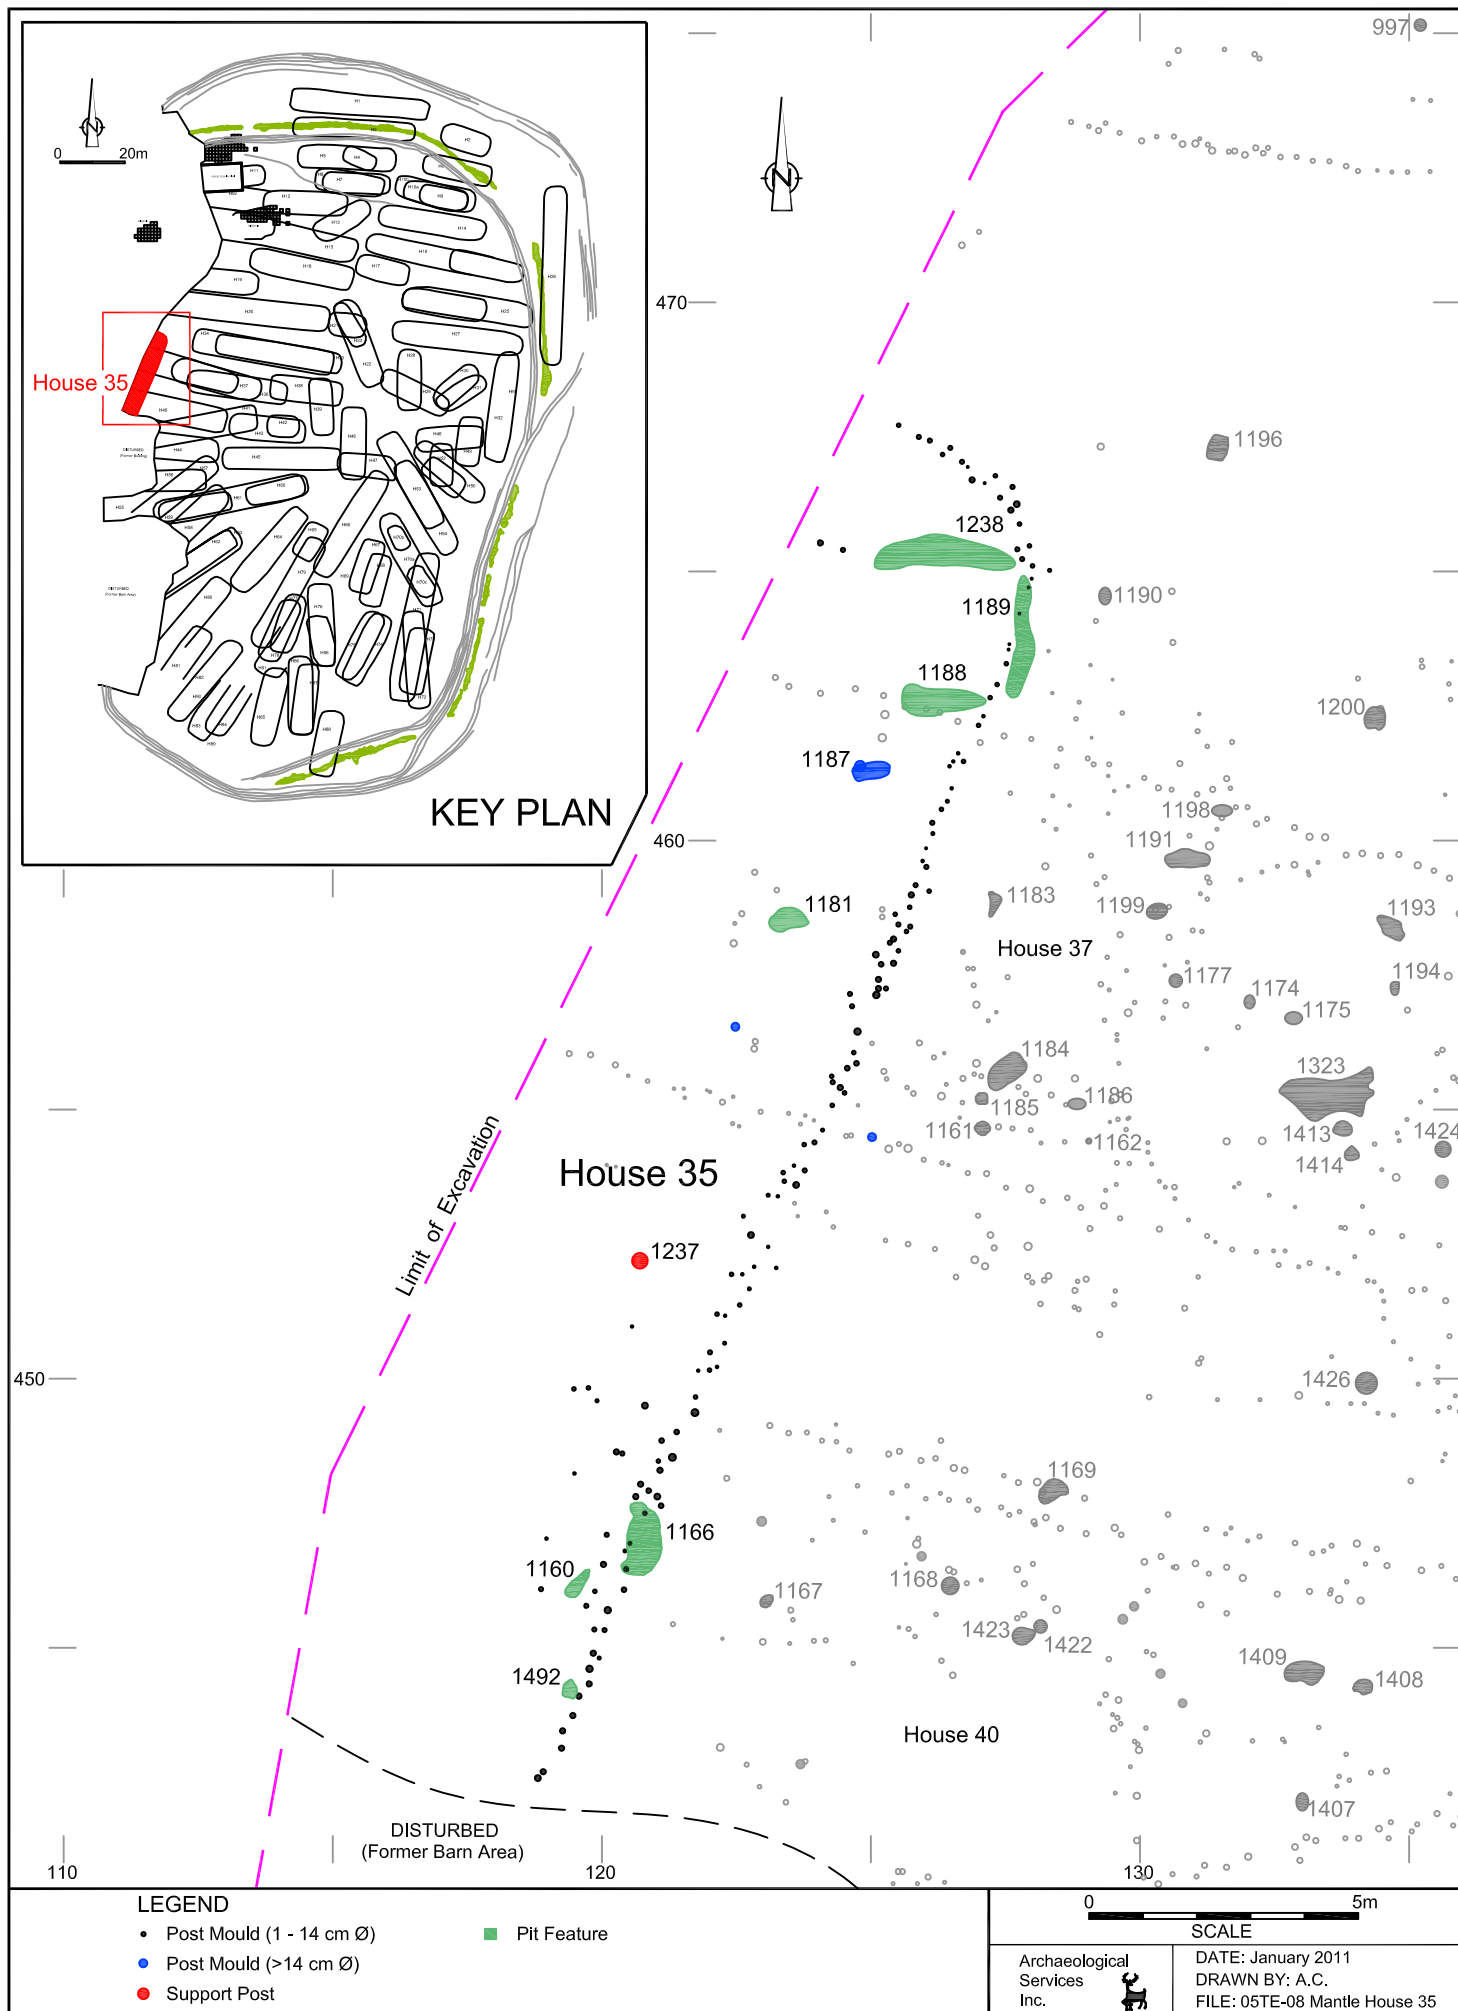

Figure 21: Plan View of House 25

ground and the creation of this pit feature removed any evidence of the posts, or this feature was located in a doorway leading into the house in which case no posts would be present.

This house was occupied during the late phase of the site. House 37 was part of the early occupation phase since it also overlapped late phase House 35. A probable occupation sequence for this section of the site is as follows. House 37 was contemporary with House 33 to the north as well as 40 and 43 to the south in the early phase (Figure 6), and these houses were later replaced with Houses 34, 35, 36 and 41 in the middle and late phases of the site (Figure 7).

### **House 37**

House 37 was part of the early phase group of houses at the site (Figure 5). It was located in the central area of the village on the west site overlooking Stouffville Creek (Figure 5). This house was oriented 107° east of north approximately perpendicular to the top of slope. Other houses in this early group include 15, 18, 19, 20, 33 and 40, among others. The orientation of those houses ranges from 95° to 103° east of north, which suggests that the early houses in this area were built perpendicular to the slope and parallel to each other.

This house was not completely exposed as the west end would have been located past the development setback and limit of excavation (Figure 5). The excavated portion of this house was 37.7 metres long and 7.6 metres wide covering an area of 247 m<sup>2</sup> (Table 1). The east end of the house was rounded in shape. A maximum house length of 40.5 metres was estimated by assuming that the west end was located on the top of the slope. Assuming a maximum length of 40.5 metres, the total enclosed area of the house would have been approximately 308 m<sup>2</sup>.

The walls of House 37 were made up of posts placed in a single row with some posts offset from the line (Figure 20). The average density of wall posts was 2.7 per metre. Two other single rows of posts were found inside the house parallel to the walls. These rows were approximately one metre from the walls, and they probably formed part of the internal house framing and bunk lines. A single curved row of posts crossing over the middle section of the house could have been the original west end from when the house was first built. The house was later extended west to the top of slope. There was a gap in the rows of posts composing the bunk lines at the first west end of the house, which suggests that this house was lengthened and not shortened. If it had been shortened, then posts aligned with the bunk lines would have been present where the gaps were found. Assuming it was only extended to the west, the original length was 25.6 metres enclosing an area of 182 m<sup>2</sup> (Table 1).

There were twenty-three pit features, nineteen support posts and one hearth found within the walls of this house (Appendix B). Since there is a large area of overlap with House 36, many of these features and posts could be associated with either house. All the features and posts contained within the walls of this house and located west of House 36 would be contemporary with House 37 with the exception of Feature 1181 and Post 1187, which were found in the area overlapping this house and House 35 (Figure 21).

### **House 38**

House 38 was another early occupation phase house oriented perpendicular to the top of slope overlooking Stouffville Creek (Figures 5 and 6). It was located five metres east of the estimated east end of House 37 and 2.8 metres south of House 33. It partially overlapped the end of House 36 as well as the north end of House 39. Both those houses were constructed during the late phase of occupation (Figure 7).

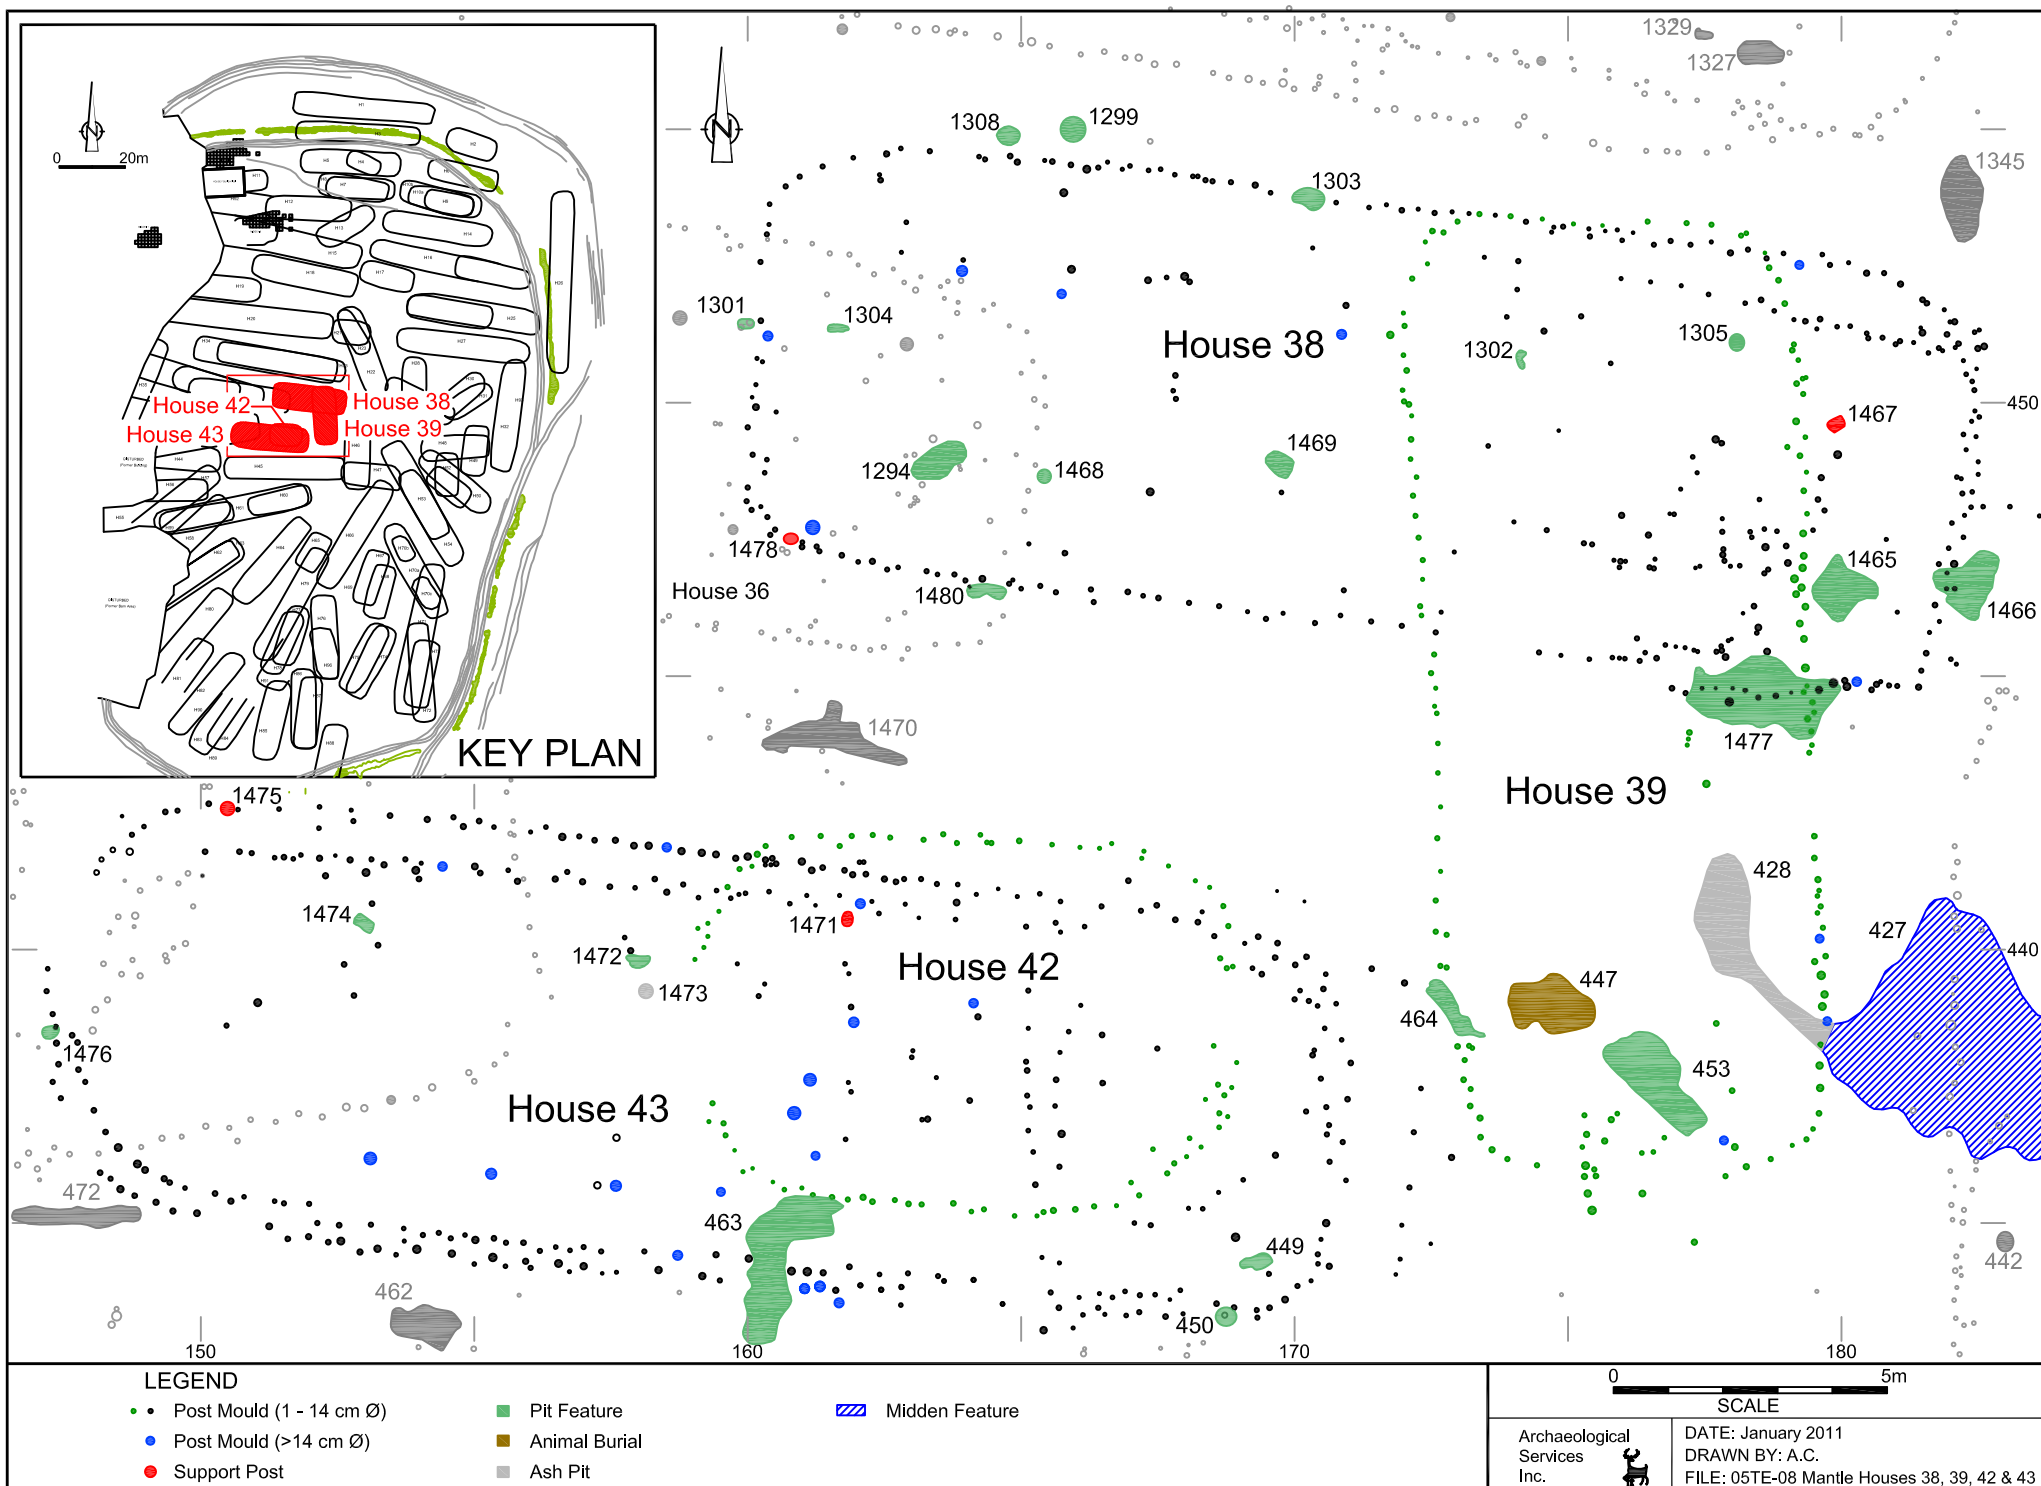

Figure 22: Plan View of Houses 38, 39, 42, and 43

This house measured 22.4 metres long and 7.7 metres wide, enclosing an area of 164 m<sup>2</sup>. It was oriented 97° east of north (Table 1). The walls were slightly tapered and squared off at each end and had a total density of 2.9 posts per metre, with single rows of posts used to close them off (Figure 22). There were additional posts found at the east end, perhaps because that section of the house needed strengthening or had been repaired. A 1.9 metre wide opening for a doorway was found midway along the south wall. Another smaller opening 1.1 metres wide was located in the west end. A short row of posts oriented east-west was found in the east end of the house approximately 1.3 metres from the north wall, and these could have been part of a short bunk line. Other posts of unknown function were also found within the area of this house.

House 38 contained eight pit features and only two support posts, which indicates that this house may not have been occupied for very long or that it was a special purpose structure. Only three of the features were found in an area of House 38 that did not overlap another house (Appendix B).

This house was oriented at a similar angle to other early houses on the west side of the site, and portions of this house overlapped late phase House 36 and 39. Given these observations, House 38 was probably occupied in the early phase of the village (Figure 18).

### **House 39**

House 39 was one of the two late phase houses that overlapped House 37 (Figure 5). In looking at the late phase site plan (Figure 7), the location, size and orientation of this house were all dependent on this house fitting in the space defined by Houses 22, 34, 36, 42 45 and 46. As discussed above, this was a late phase house and constructed at a time when houses at the site were built to best fit the remaining spaces in the palisaded village. The result was a more random settlement pattern different from the early phase pattern of houses oriented perpendicular to the slope and parallel to each other (Figure 6).

House 39 has a rectangular shape in plan view with slightly rounded corners (Figure 22). It was 17.5 metres long and 6.9 metres wide, covering an area of 117.2 m<sup>2</sup> (Table 1). The house was oriented almost straight north at 356° east of north. It was situated 2.1 metres east of House 43, 1.4 metres south of House 34 and 2.2 metres west of House 46. This is consistent with the average spacing of approximately two metres between structures seen throughout the late phase of occupation (Figure 7).

The walls were constructed by placing posts in a single row, resulting in a total average wall post density of 2.9 posts per metre. Additional posts were possibly used to strengthen the east wall where a 1.5 metre wide doorway was located. Another possible doorway measuring 2.0 metres wide was located in the middle of the south wall. A cluster of posts within the house near that doorway could have served as framing for an entrance structure inside the house (Figure 22).

This house contained a small number of features including five pits, a feature containing animal bone, and an ash pit that was connected to a small midden-like feature adjacent to the east wall. Features 1302 and 1305 were located in the area of the house that overlapped House 38, so it was not possible to confirm their association with either house. Feature 1477 was found in the area where the east wall of this house crossed the south wall of House 38. Posts for both walls were seen in the feature fill, so it was likely that this feature predated both houses (Figure 22 and Appendix B).

House 39 was a small structure that may have only housed a few people during the late occupation phase of the site, and may in fact have been semi-permanent or temporary in nature (Figure 7). Given the low wall post density and lack of centrally-aligned features, the occupation of this house may have been relatively short-lived and the features found in this house may have been the result of exterior activities

pre- or post-dating the house. House 39 was centrally located in the village and, along with Houses 46 and 28, was oriented on an almost straight north-south axis.

### **House 40**

House 40 was an early occupation phase house located on the west side of the village, perpendicular to the top of the bank (Figures 5 and 6). It had been disturbed by the construction of farm buildings and was partially located beyond the development setback and limit of excavation. As was the case for House 37, the location of the west end of this house was estimated based on the distance to the top of bank.

The exposed portion of the house was 32.5 metres long and 7.8 metres wide with an enclosed area of 245 m<sup>2</sup> oriented 102° east of north (Table 1). Assuming that the west end was located on the top of bank, the estimated maximum length of the House was 35 metres (covering an area of 258 m<sup>2</sup>). It should be noted that for the maximum area estimation the plan view shape and size of the west end was assumed to be the same as the exposed east end.

The wall posts of House 40 were placed in pairs offset from each other with a relatively low average wall post density of 2.8 posts per metre. At the east end of the house, the walls were curved inward and a single row of posts was used to construct the end (Figure 23). There was no obvious opening in the wall or end that would indicate the presence of a doorway. The doorway into this house must have been at the west end or in a section of wall that was not exposed. The north wall of this house appears to have been rebuilt at one point in time as there were two parallel walls 1 meter apart on that side of the structure.

### **House 41**

The west end of this house was heavily disturbed by the construction of a barn, part of the farm complex that had been located on the property (Figure 5). The remaining portion of House 41 was 32.9 metres long and 7.8 metres wide covering an area of 236 m<sup>2</sup> and was oriented 78° east of north (Table 1). To estimate the maximum length of the house, if the north wall was extended southwest to meet the top of slope leading down to Stouffville Creek, and if a minimum distance of one metre between the houses is assumed, then the estimated maximum length of House 41 was 41 metres and the maximum enclosed area was 327 m<sup>2</sup>.

The wall posts for this house were placed in offset pairs with some additional posts added to portions of the north wall for possible repair or strengthening (Figure 23). This resulted in a total wall post density of 2.9 posts per metre. Both walls were rounded with a flat end at the east end and a single row of posts forming the end. There was no clear doorway in the exposed sections of the walls or end, so a doorway was presumably located in the western section of the house.

House 40, 43, and 44 were occupied during the early phase of the village (Figure 6), and House 41 overlapped these houses, which means that House 41 must postdate them (Figure 7). Most of the features contained within this house were found in areas overlapping other houses; however, there is a distinct cluster of posts that lies only within the west half of House 41. This cluster, along with Feature 1415, could have been the remains of an above ground sweat lodge built inside the longhouse (Figure 23 and Appendix B). Only three pit features and three support posts contained in this house were located in areas that did not overlap another house. One hearth was found in this house, but, due to its location, it could have been associated with either this house or House 40.

## **House 42**

House 42 was a small, late occupation phase house located 2.7 metres east of House 41 and overlapping with House 43 (Figures 5 and 7). It measured 9.8 metres long and 6.7 metres wide enclosing an area of 59 m<sup>2</sup> making it the smallest house on the site. It was oriented 91° east of north (Table 1).

This house was located almost entirely within the footprint of House 43 (Figure 22). Since House 43 was overlapped by House 41 (a late phase house), House 43 is probably an early phase structure. House 42, which is located over top of House 43, must then be a late occupation phase house. It was surrounded by late phase Houses 36, 39 and 41, as well as House 45, which was occupied in the early and late phases of the village.

House 42 was built using posts placed in a single row with some extra posts in the southeast and northwest parts of the house (Figure 22). The average wall post density was 3.1 posts per metre. The east end was semi-circular in plan view shape while the west end was flatter. There was a 1.4 metre wide opening in the east end and a 2.4 metre wide opening in the west end that were probably both doorways.

No pit features were found, and there was only a single support post that could have been associated with this house or House 43 (Figure 22 and Appendix B). Given the paucity of features associated with this house as well as its unusual shape, House 42 may have been a semi-permanent or special purpose structure.

## **House 43**

House 43 was an early phase house that was overlapped by Houses 41 and 42 (Figures 5 and 6). It was another house in the early phase group located on the west side of the site oriented approximately perpendicular to the top of slope. This house was located 5.5 metres south of House 38 and 1.2 metres east of House 40.

House 43 was 23.8 metres long and 7.9 metres wide, covering an area of 171 m<sup>2</sup> and oriented 96° east of north (Table 1). This house appears to have been partially rebuilt, as indicated by double walls on the south side and west end with an average density of 5.0 posts per metre. Wall posts were placed in a single row throughout most of the house walls, while other sections were built by placing posts in offset pairs (Figure 22). There was a row of interior posts parallel to the north wall about 0.85 metres from that wall that could have been part of a bunk line and internal framing for the house. The distance between the rows of posts along the south wall was only 40 centimetres, which was likely not enough space for a bunk line. These probably represent the rebuilding of the south wall. There were also four large posts that formed a line parallel to the south wall at 1.2 metres from it, and these may have been the framing for a bunk line. The ends of House 43 were both round in shape and there was a 1.9 metre wide opening for a doorway in the west end.

Five pit features, two support posts and an ash pit found within this house. Only Feature 1474 and support posts 1471 and 1475 were located in areas of the house that overlapped with other houses, so it is uncertain with which house these were associated. Feature 463 was a pit feature that crossed through the south wall of the house (Appendix B). Since no evidence of posts was found in or below the fill of this feature, it is unclear whether it is associated with the house.

## **House 44**

House 44 belongs in the early group of houses overlooking Stouffville Creek (Figure 6). It was the westernmost house in a line of three houses oriented west to east that included Houses 45 and 47 (Figure

5). The west end was disturbed by the construction of the barn of the farm complex on the property, which also impacted House 41 (see above). As the west end was disturbed, it was not possible to measure the full length of the house. The exposed portion of the house was 20 metres long, 8 metres wide, and covered an area of 147 m<sup>2</sup> oriented 95° east of north (Table 1). Assuming that the end was located near the top of the slope and that it was the same shape and size as the exposed east end, then the estimated length of the house was 31 metres and it would have covered an area of 234 m<sup>2</sup>.

The walls of this house were constructed by placing posts in pairs offset from each other, with an average wall post density of 3.7 posts per metre. The east end was rounded in shape with a 1.3 metre wide doorway in the centre (Figure 23). There was no indication of any interior bunk lines along the north wall; however, there was a line of six larger posts parallel to the south wall. This line was 1.6 metres from the south wall and may have formed a bunk line. A circular cluster of posts was located on the central axis of the house 9.2 metres from the east end. These posts could have part of a rack or cooking structure or perhaps an above ground sweat lodge similar to the one seen in House 41 (see above). There was neither a hearth nor fired soil within this post cluster, so it is not possible to determine the function of the structure that left this post pattern.

House 44 was overlapped by late phase House 41. It was part of the overall early occupation phase pattern of the site where houses were perpendicular to the slope and parallel to each other (Figure 6). Houses in that group within the immediate vicinity of House 44 are Houses 37, 40, 43, 45 and 56.

### **House 45**

This house was situated between House 44 (located 1.3 metres to the west) and House 47 (adjacent to the east end) (Figure 5). The east end was not very clearly defined, and no posts were identified where it would have overlapped House 46 (Figure 24). While it is possible that this was an open-ended house, it is more likely that the posts were disturbed by the later construction of Houses 46 and 47. If this is the case, then House 45 can be assigned to the early phase of village occupation (Figure 6). The sequence of house construction in this area of the site suggests that House 47 was probably a middle phase house that was later replaced by House 46. This central portion of the village contains the most dynamic and changeable history of occupation in the village, and as a result it was not always possible to definitively assign houses to one phase or another.

House 45 was 35.6 metres long, 6.8 metres wide, enclosed an area of 237 m<sup>2</sup>, and was oriented 90° east of north (Table 1). The walls of House 45 were constructed from posts placed in a single row that was rounded at the west end (Figure 24). The average density of wall posts was relatively low at 2.8 posts per metre. A four metre wide opening or doorway was found in the west end that may have been closed off using the two posts found within the doorway. There was evidence of the presence of bunk lines along the north and south walls of the house. Eight large posts along with some smaller interior posts formed a line 1.3 metres from the north wall, and there were twelve large posts in a linear pattern approximately 1.2 metres from the south wall.

Another circular pattern of posts similar to the one seen in House 44 was located along the central axis of the house in the middle portion (Figure 24). These posts may have supported a cooking rack or structure, or this could be another above ground sweat lodge. No hearth features were identified in this house. Other features found included nine pits, and eight support posts and other large posts (Appendix B).

This house was occupied during the early phase of the village (Figure 6). House 47, adjacent to the east end, intersects the south wall of this house and was built later in the early phase or perhaps in the middle phase. The south wall of House 45 terminated at the end wall of House 47 with no sign of either the north

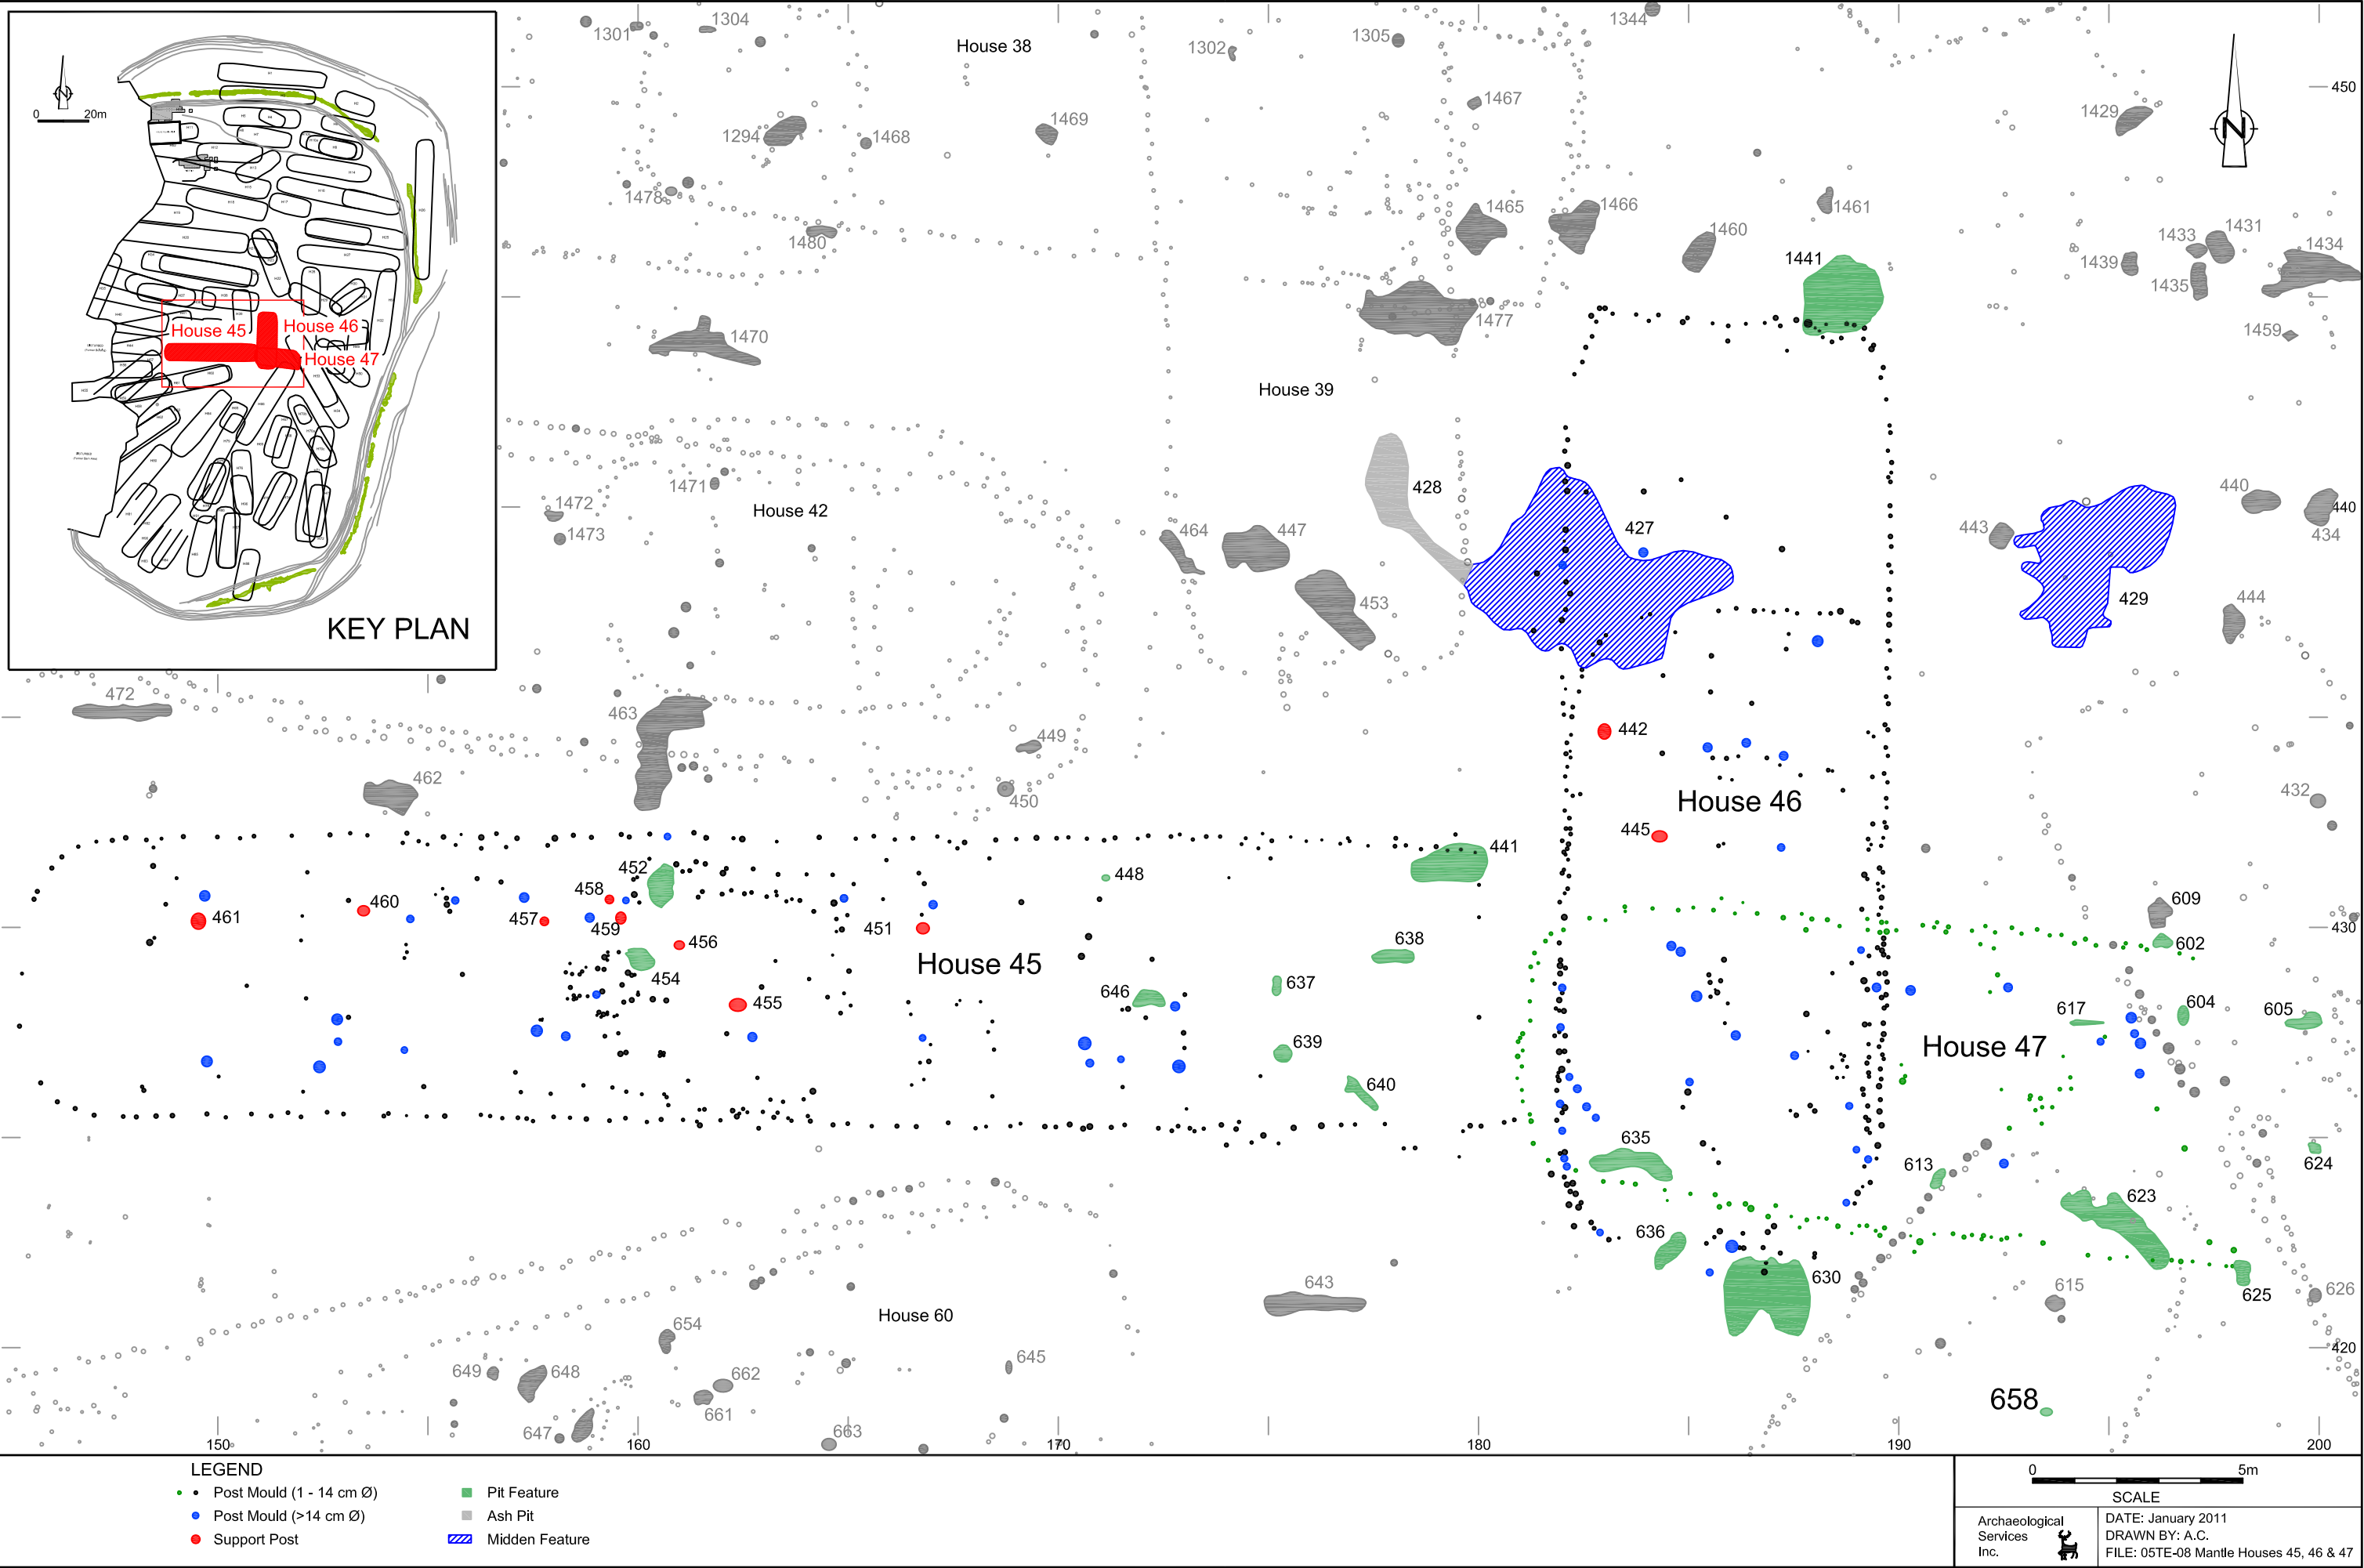

Figure 24: Plan View of Houses 45, 46 and 47

or south walls intersecting the west wall of House 46. This supports the idea that House 46 was built much later than House 45.

### **House 46**

House 46 was a late phase house constructed after House 47 was dismantled (Figures 5 and 7). Its was 21.9 metres long, 7.4 metres wide, covered an area of 165 m<sup>2</sup>, and was oriented 1° east of north (Table 1). This house appears to have been built in two stages, as indicated by a curved row of posts crossing the house that represent the original north end (Figure 24). The south end remained constant through both construction events, so the initial house length of the house was 15 metres enclosing an area of 111 m<sup>2</sup>. It was later extended 6.9 metres north to its maximum length.

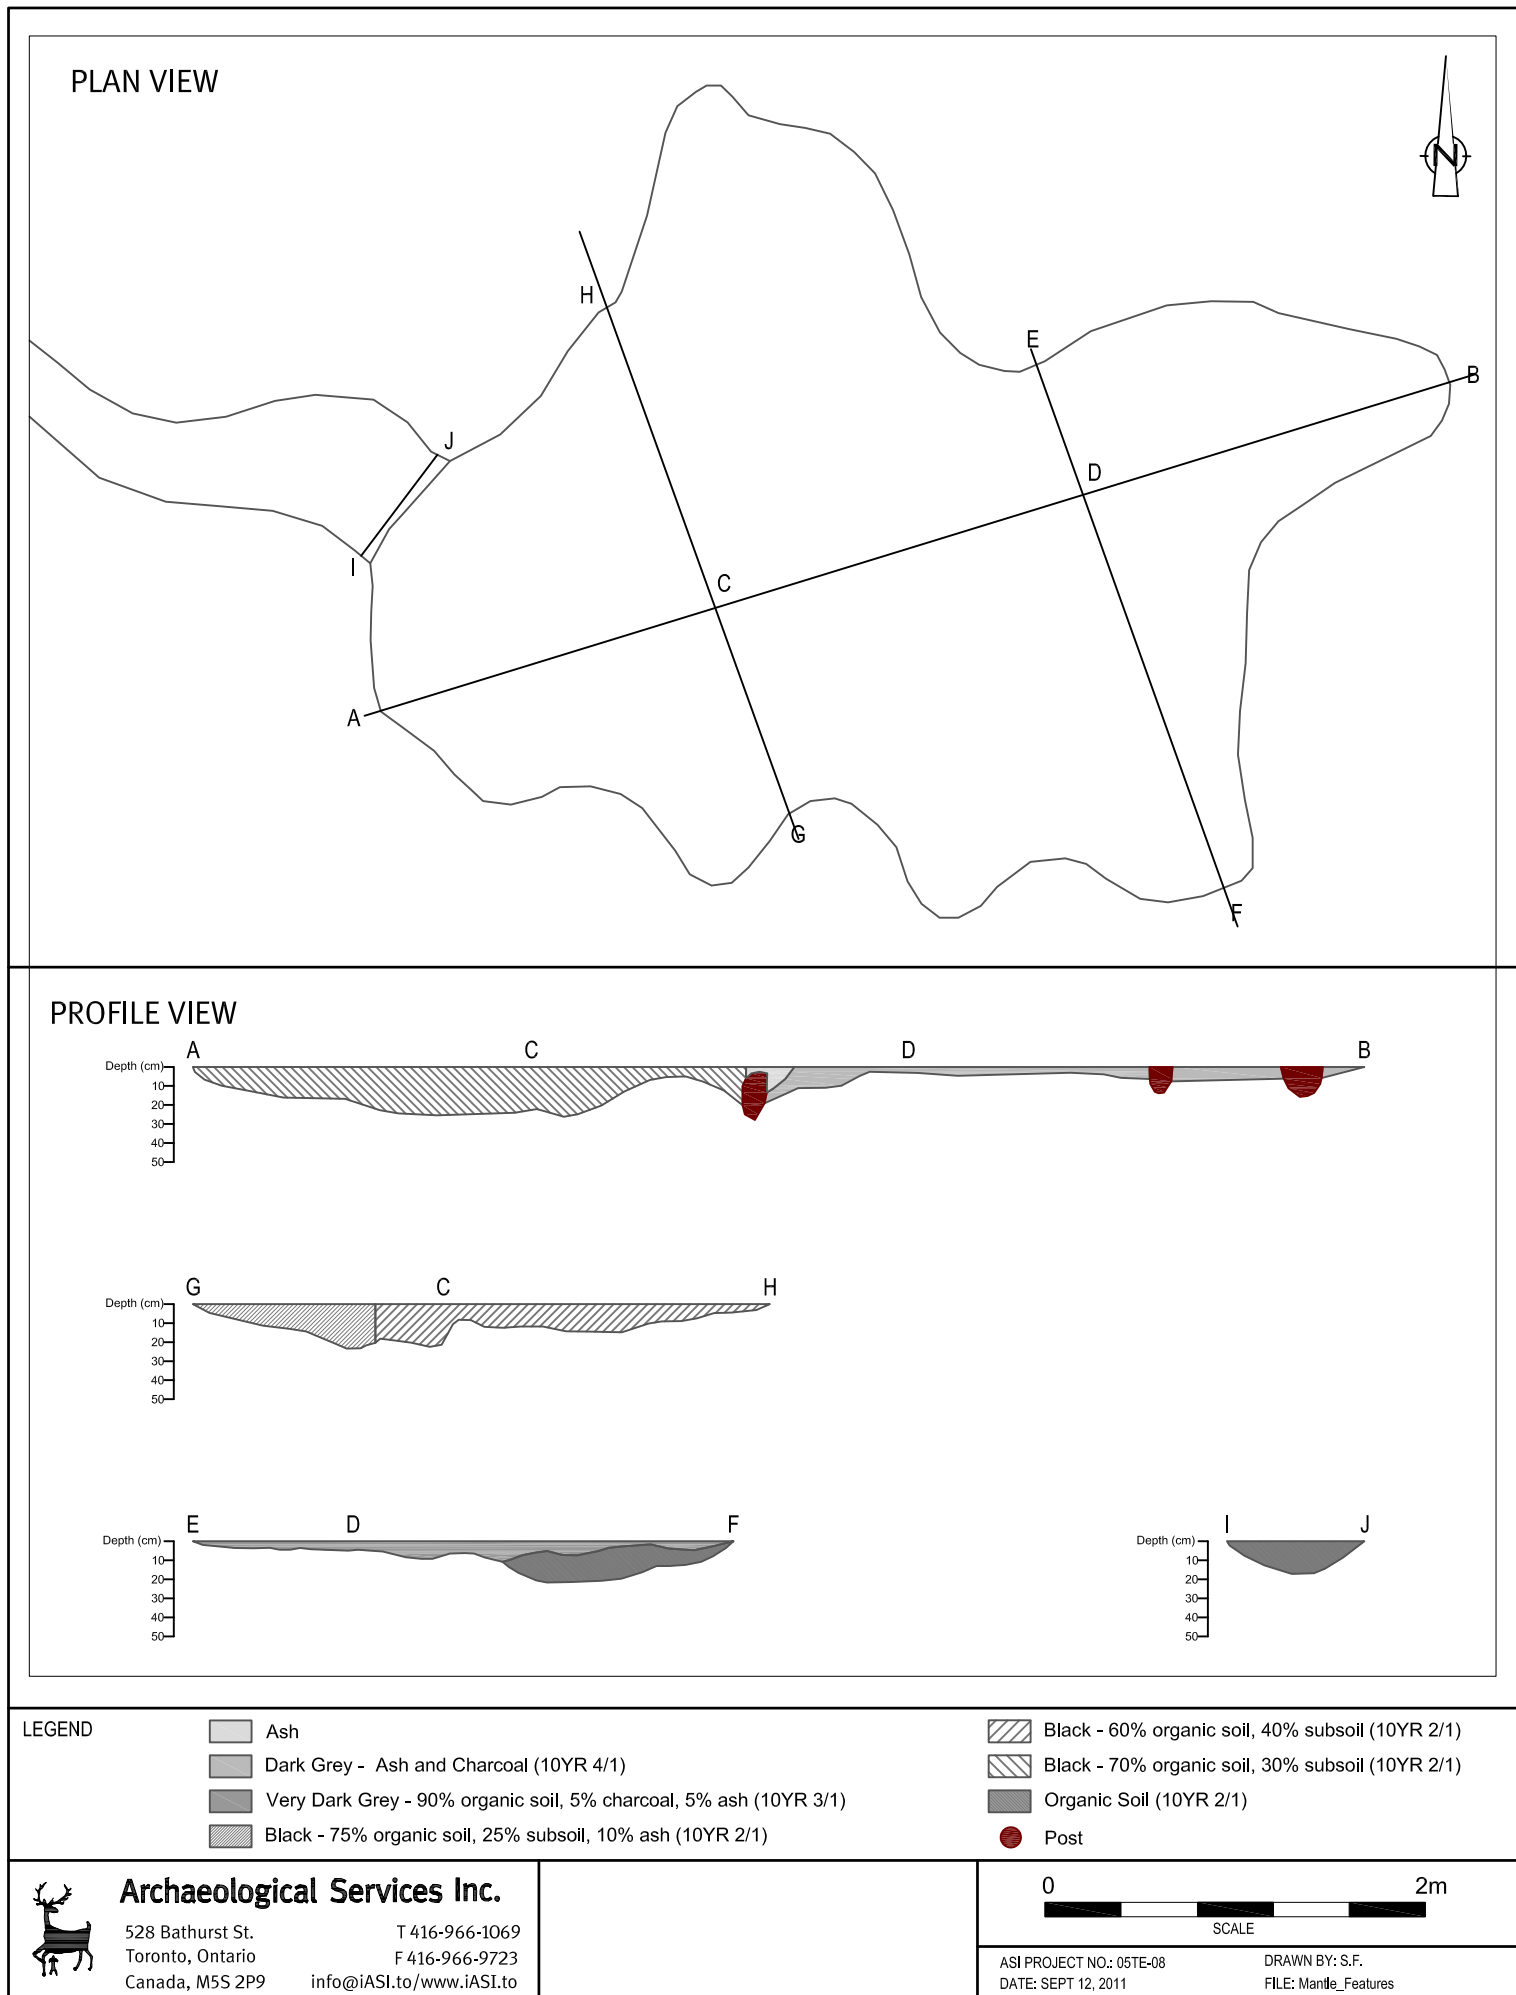

The wall posts were set in pairs, and this pattern is very clear in the north half of the east wall (Figure 24). Given that this post pattern appeared consistent throughout the area of wall extension, it is likely that the entire north portion of the east wall was rebuilt when the house was extended. More posts were added to the west wall for support in the area of the extension, though the remainder does not appear to have been rebuilt. The north end of the extension was different in plan view from the initial north end or south end. The side walls were slightly tapered with a single row of posts in a flattened arrangement. In contrast, the initial north end and south end were more rounded in plan view. A 2.3 metre wide opening in the south end appears to have been the only doorway into this house. The total average wall post density of both the extension and original house was 4.3 posts per metre (Table 1).

The west wall was oriented so that it intersected midden-like Feature 427 (Figure 25). There was no evidence that the posts were set into the fill of the feature; however, post mounds relating to these wall posts were found in the subsoil below the feature. Therefore, this house predates Feature 427. There were no interior pit features found within the walls of this house that could be directly associated with the house. Two support posts were located south of the initial north end of the house, and these likely were used in the house framing.

This house, along with Houses 39 and 42, were part of the later occupation of the village when houses were placed in order to best fit into the remaining open spaces within the palisaded enclosure of the village (Figure 7).

### **House 47**

House 47 was an early occupation phase house located adjacent to the east end of House 45 (Figures 5 and 6). It measured 19.4 metres long and 7.3 metres wide, and covered an area of 123 m<sup>2</sup> oriented 94° east of north (Table 1). This house was impacted by the construction of three later houses. House 46 overlapped the west half of this house, while the east half was obscured by Houses 53, 54 and 66. The east end of House 47 was not found and was likely disturbed by the construction and occupation activities of Houses 53 and 54. Since the east end was unobservable, the length measurement was based on the assumption that the eastern end started at the most eastern post of the south wall, and that it had the same shape as the west end.

Sections of the house walls were made up of posts placed in a single row while other sections had offset post pairs (Figure 24). The average wall post density was 3.0 posts per metre. The west end was comprised of a single row of posts placed on a slightly curved path. There were no openings for doorways in the walls or west end of the house.

Four pit features were contained within the footprint of this house, but only Features 613 and 617 were found in a portion of the house that did not overlap the area of another house. These features can be presumed to be contemporary with House 47 (Appendix B).

### **Houses 48, 49, 50, 51 and 52**

These houses were part of a small group located in the central area of the village, closer to the east side and adjacent to the late phase palisade (Figure 5). Houses 48, 49, 51 and 52 were all similar in shape (plan view) and size with lengths ranging from 13.4 to 20.4 metres. House 50 was 26.3 metres long and had semi-circular ends (Table 1 and Figure 26). Due to the overlapping placement of these five houses, only two could have existed at any given time. It is probable that they were semi-permanent in nature and constructed no earlier than the early-to-middle phase of the village's occupation (Figures 6 and 7). In the original village plan the area occupied by these houses was probably intended to be an open plaza.

House 48 was 20.4 metres long and 7.2 metres wide (Table 1). It enclosed an area of 139 m<sup>2</sup> and oriented 86° east of north. The posts were placed in a single, low-density row (2.2 posts per metre), and the pattern of posts shows that this house was extended once with an addition built on the west end (Figure 26). The curved line of posts that crossed over the middle portion of the house was the initial west end, which was later extended 6.6 metres to a maximum length of 20.4 metres. The original length was 13.8 metres and the house covered an area of 92 m<sup>2</sup>. The width remained constant as the house was extended. Doorway openings were observed in both west ends of the house. A 1.3 metre wide opening was found in the extension end and a 1.7 metre wide opening was found in the first west end. This location of the east end shares the same alignment as the east wall of House 49. Due to the overlapping nature of this group of houses, House 48 could not have been contemporary with Houses 49, 50 and 52.

House 49 measured 15.1 metres in length, 7.3 metres in width and covered an area of 104 m<sup>2</sup>. It was oriented 7° east of north (Table 1). This house was rectangular in plan view with the ends of the walls curved inwards to round the corners and a single row of posts used to close off the ends (Figure 26). The average wall post density was 2.9 posts per metre. A two-metre wide doorway opening was found in the south end of the house. The walls were constructed by placing posts in a single row with a few extra posts on the west wall for additional strengthening.

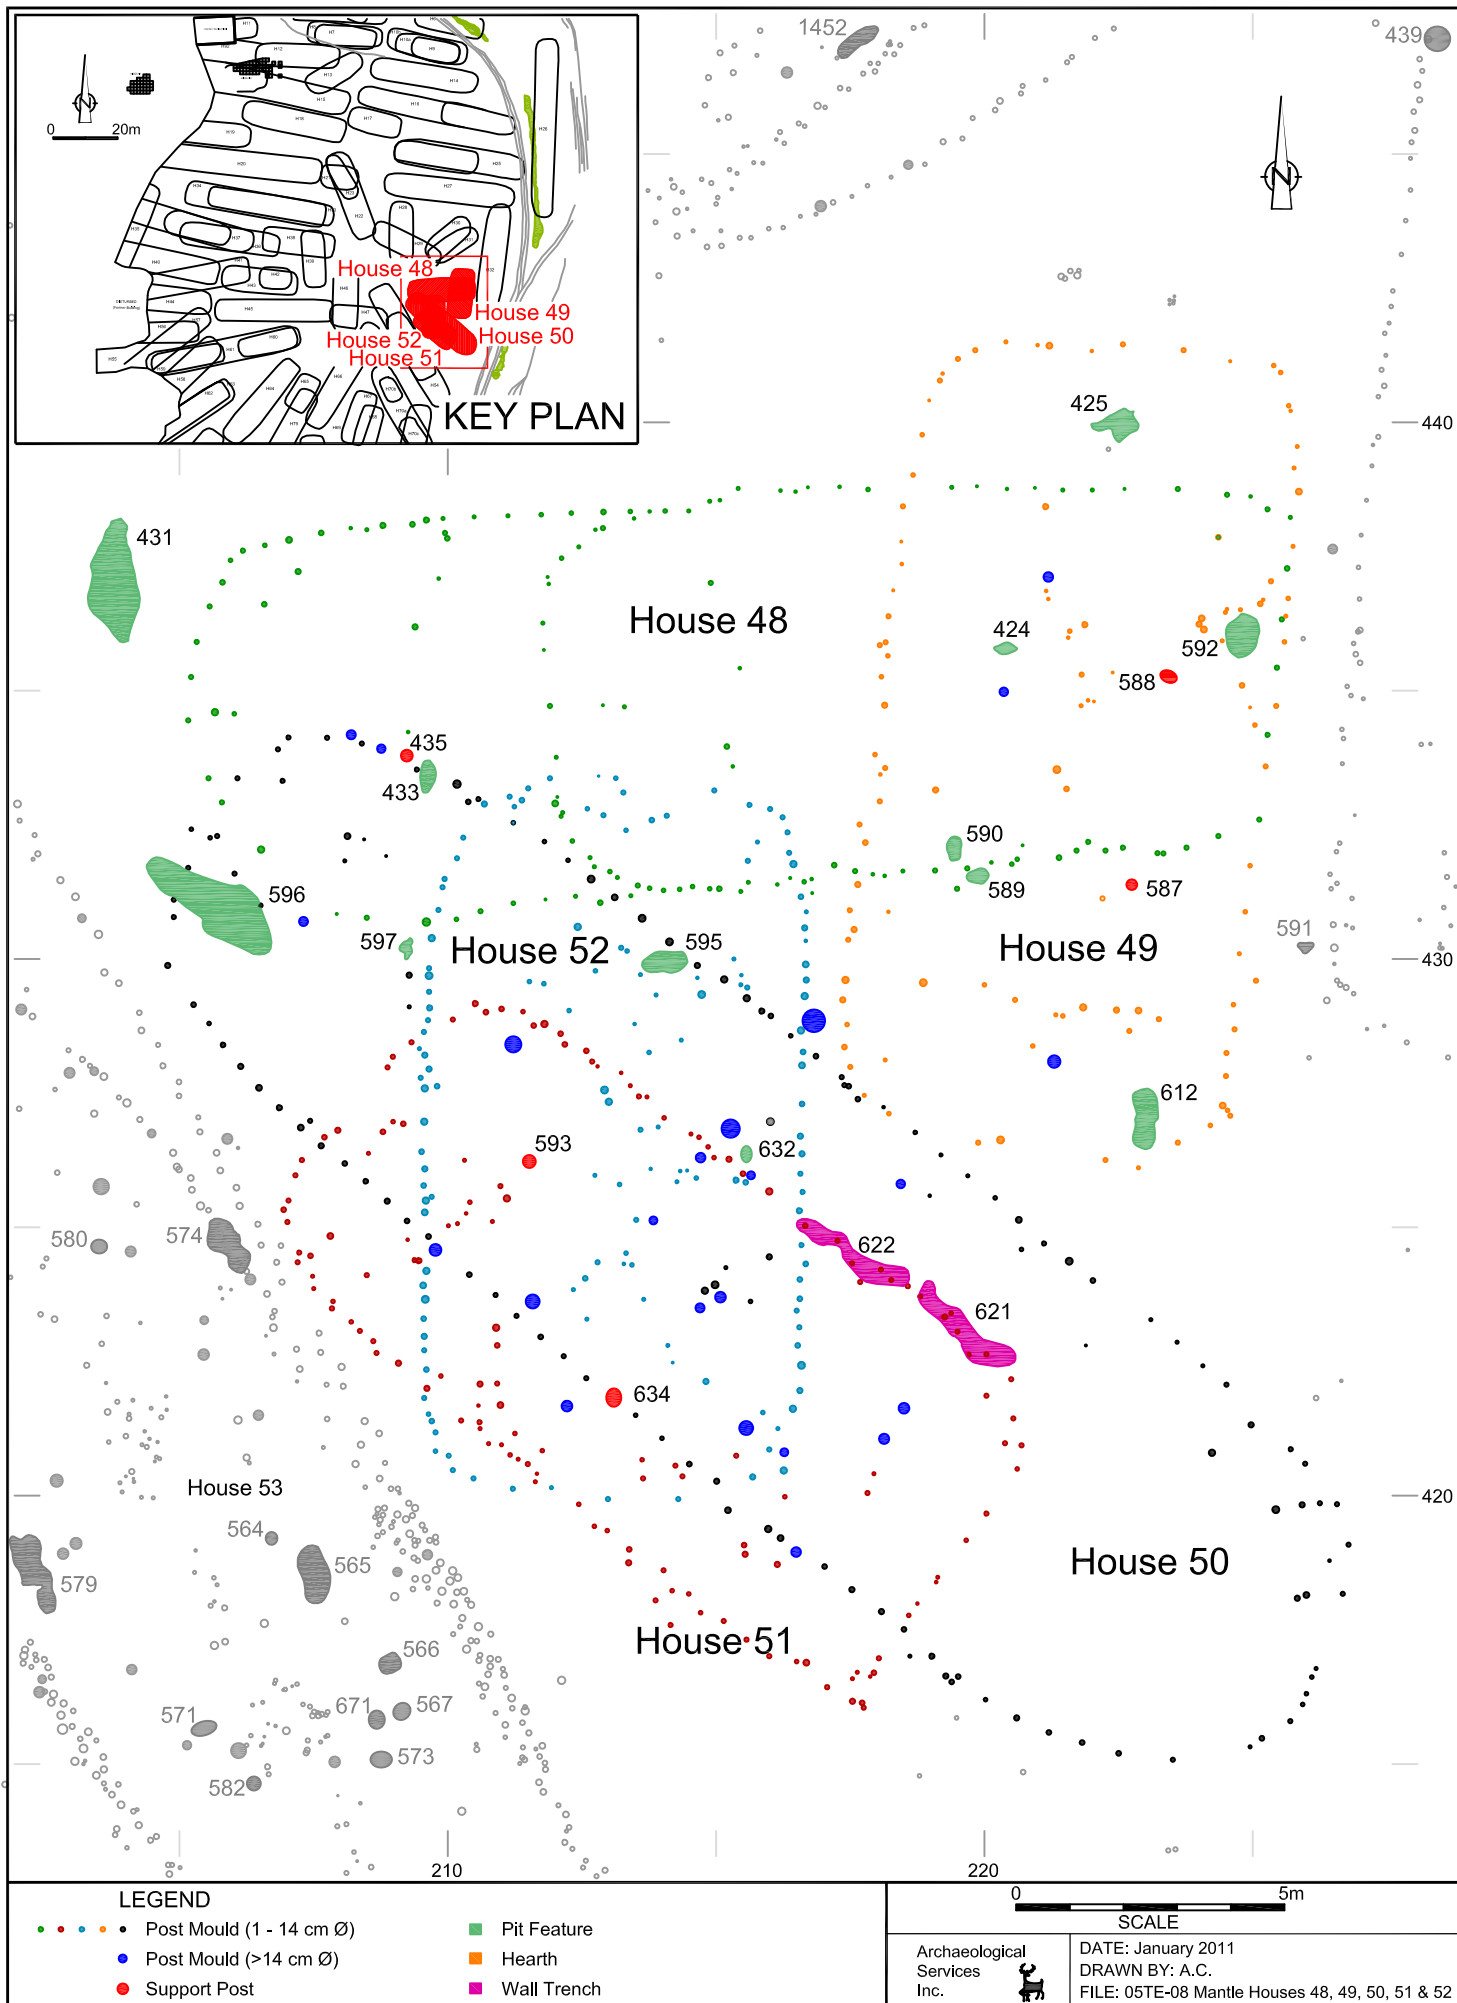

Figure 26: Plan View of Houses 48, 49, 50, 51 and 52

Six pit features and two support posts were contained within this house. Three of those features and one support posts were in the area common to both House 48 and 49. Pit features 425, 589 and 612 could be considered contemporary with this house since they were located in portions of the house that did not overlap (Figure 26 and Appendix B).

The southwest corner of House 49 touches a portion of the middle section of the northeast wall of House 50. Because they are situated close together and at different orientations, is unlikely that Houses 49 and 50 would have co-existed. House 49 therefore was probably used during the early to middle phase of occupation (Figure 6).

House 50 is the longest house in this group of five. It was 26.3 metres long, 7.2 metres wide, enclosing an area of 175 m<sup>2</sup> and oriented 128° east of north (Table 1). Despite its large size, the density of wall posts used in its construction was no greater than the other houses in this group (2.5 posts per metre). The house was constructed by placing posts in a single row in both walls and ends (Figure 26). The ends were semi-circular in plan shape, unlike the other houses in this group that had more rectangular shaped ends. There was a 1.3 metres wide opening in the centre of the northeast end that could have been used as a doorway.

Two pit features (596 and 597) were contained within this house and were not found in areas that overlapped other houses (Appendix B). Therefore it is possible that those features were contemporary with House 50. Given the overlapping pattern of the five houses in this group, House 50 would not have existed at the same time as any of the other four and likely belonged to the late phase of occupation (Table 8).

House 51 was situated partially within the footprint of House 50 and oriented almost parallel to it at 125° east of north (Figure 5). It measured 14 metres long and 6.8 metres wide enclosing an area of 88 m<sup>2</sup> (Table 1). Some sections of the walls were built by placing posts in pairs offset from each other, while other sections had a single row of posts. The average post density was 2.9 posts per metre. The ends of the walls were curved inward with a single row of posts used to close off the ends of the house. A doorway opening 1.4 metres wide was located in the northwest end and appears to have been the only entrance into the house (Figure 26).

This house overlapped with Houses 50 and 52 and contained no features. There were two wall trench features (621 and 622) along the northeast wall that would have been created during the construction of the house (Figure 26 and Appendix B). House 51 could not have stood at the same time as Houses 50 or 52 because they overlapped, but it may have been contemporary with either House 48 or 49 (Figure 6).

House 52 was the smallest house in this group measuring 13.4 metres long and 7 metres wide enclosing an area of 87 m<sup>2</sup> (Table 1). It also had the highest wall post density, averaging 3.2 posts per metre. It was oriented straight north at 0° approximately parallel to House 49, which may be suggestive of a close temporal relationship. This house was rectangular in plan shape with rounded corners similar to Houses 48, 49 and 51 (Figure 26). Posts placed in a single row were used to construct the walls and the ends of the house. The only apparent doorway was a 1.9 metre wide opening in the north end.

Two features were identified within this house. Features 595 and 632 were located in a portion of the house that also overlaps House 50, so it is unclear with which house they were associated (Appendix B). House 52 could not have co-existed with Houses 48, 50 or 51 because of their overlapping positions. However, this house could have been contemporary with House 49 because of their parallel orientation (Figure 26).

Given the superimposition of these houses, as well as the relatively low density of wall posts and features contained within them, it is very likely that these houses were semi-permanent in nature and were constructed in the middle of what was formerly an open plaza area (see Section 2.5.1 below). They may

have been dismantled after use, thus opening up this central plaza area. In the late phase of occupation the plaza was filled in with longer-lived structures such as House 53 (Figure 7).

### **Houses 53 and 54**

These two houses share a similar footprint in the eastern central portion of the village (Figure 5). House 53 appears to have been constructed first, and was dismantled or burned down before the larger House 54 was built.

The central portions of these two houses were situated directly over each other with House 54 extending slightly further to the northwest and southeast. House 53 was 23.1 metres long and 7.3 metres wide covering an area of 152.3 m<sup>2</sup>, while House 54 measured 41.5 metres long and 7.5 metres wide enclosing an area of 304 m<sup>2</sup> (Table 1). The orientation angles of Houses 53 and 54 were 150° and 148° east of north, respectively.

The walls of each house were constructed using pairs of posts offset from each other with some sections with a single row of posts (Figure 27). Due to the overlap between the two structures, the average wall post density for House 53 could not be measured. House 54 had an average density of 6.2 posts per metre in those sections that did not overlap with House 53. The ends of the walls were tapered or rounded with a row of posts used to form a flat end. The south end of House 53 was made up of post pairs instead of the single row seen at the other ends.

There was a line of large posts parallel to the east walls of the houses that would have been part of the framework for a bunk line along those walls. The line was 1.6 metres from the wall of House 53 and continued into the northern portion of House 54 (Figure 27).

Eighteen pit features and eight support posts were identified within these two houses. Of those pit features, five were located in the northern portion of House 54 and three in the southern portion of House 54, and these features were likely contemporary with House 54 (Figure 27 and Appendix B). The rest of the pit features found within the overlapping area between the houses and cannot be definitively assigned to either house.

These houses were probably occupied during the middle to late phases of the site, once the plaza began to be filled in with houses (Figure 7). The northern portions of both of these houses overlapped with the east end of House 47, an early occupation phase house. All the posts found in the northern section of the east wall of House 53 had very high concentrations of charcoal, suggesting that this wall may have burned down (Appendix B). If this section of the house was destroyed by fire, then the damage may have been too extensive to just repair the wall. If that was the case, parts of the house may have been salvaged and used to build a new house (House 54).

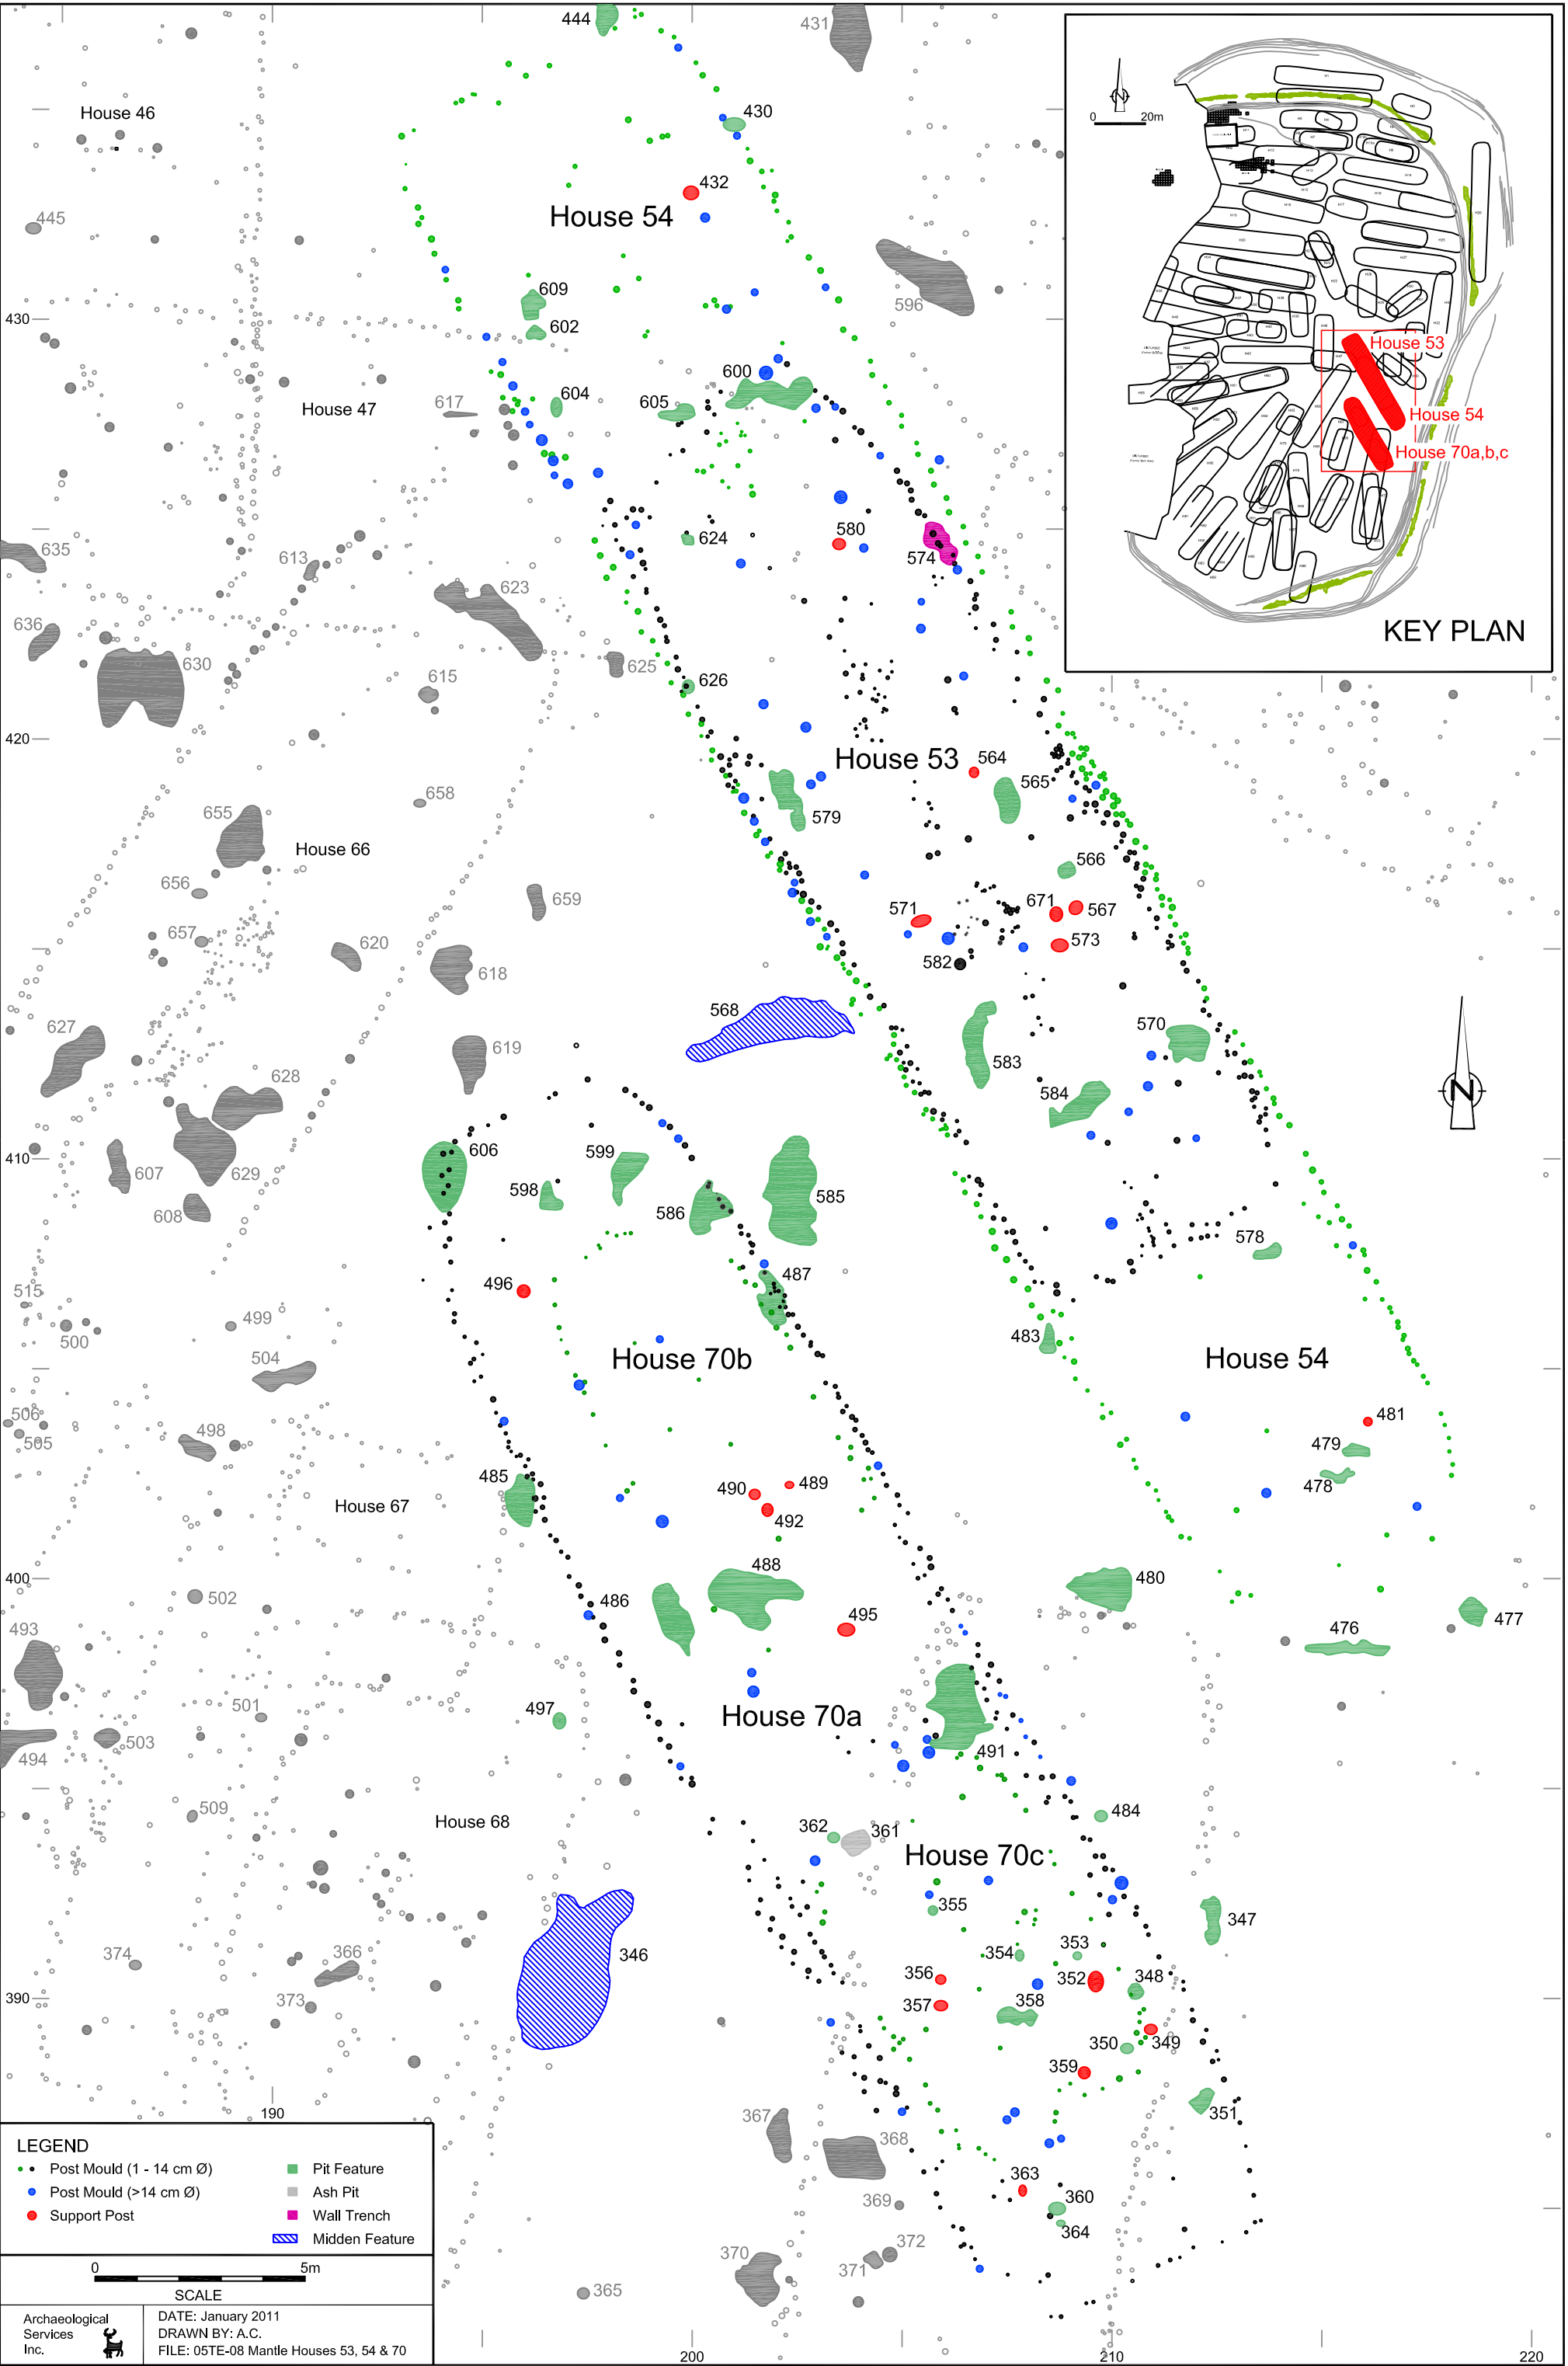

Figure 27: Plan View of Houses 53, 54 and 70

### **House 55**

House 55 was located on the west side of the site overlooking Stouffville Creek (Figure 5). It was situated parallel to the top of slope and oriented 4° east of north. The north and south ends of the house had been completely disturbed by the construction of a barn to the south and outbuilding to the north as part of the farm complex located on the property. The exposed portion was 7.5 metres long and 7.4 metres wide with an area of 53 m<sup>2</sup> (Table 1). Given its location and surrounding topography, this house may have been similar in size to House 35, which was estimated to have a maximum length of 30 metres.

The extant wall sections were constructed using posts placed in pairs offset from each other, with an average density of 3.4 posts per metre. There was a circular cluster of posts found along the central axis of the house (Figure 28), similar to the cluster in House 41 and 44 (Figure 23). This could have been a structure such as a cooking rack or an above ground sweat lodge.

Two pit features, two support posts and a hearth were contained within this extant section of the house (Figure 28 and Appendix B). House 55 may have overlapped an early phase house such as House 56, but the area where they would have intersected was disturbed by the farm building construction. The features and posts in this house were not within the overlapping area, so they should be directly associated with House 55. Since this house was oriented parallel to the top of slope (and not perpendicular, like most early phase houses in this area), it was considered to be a late occupation phase house (Figure 7).

### **House 56**

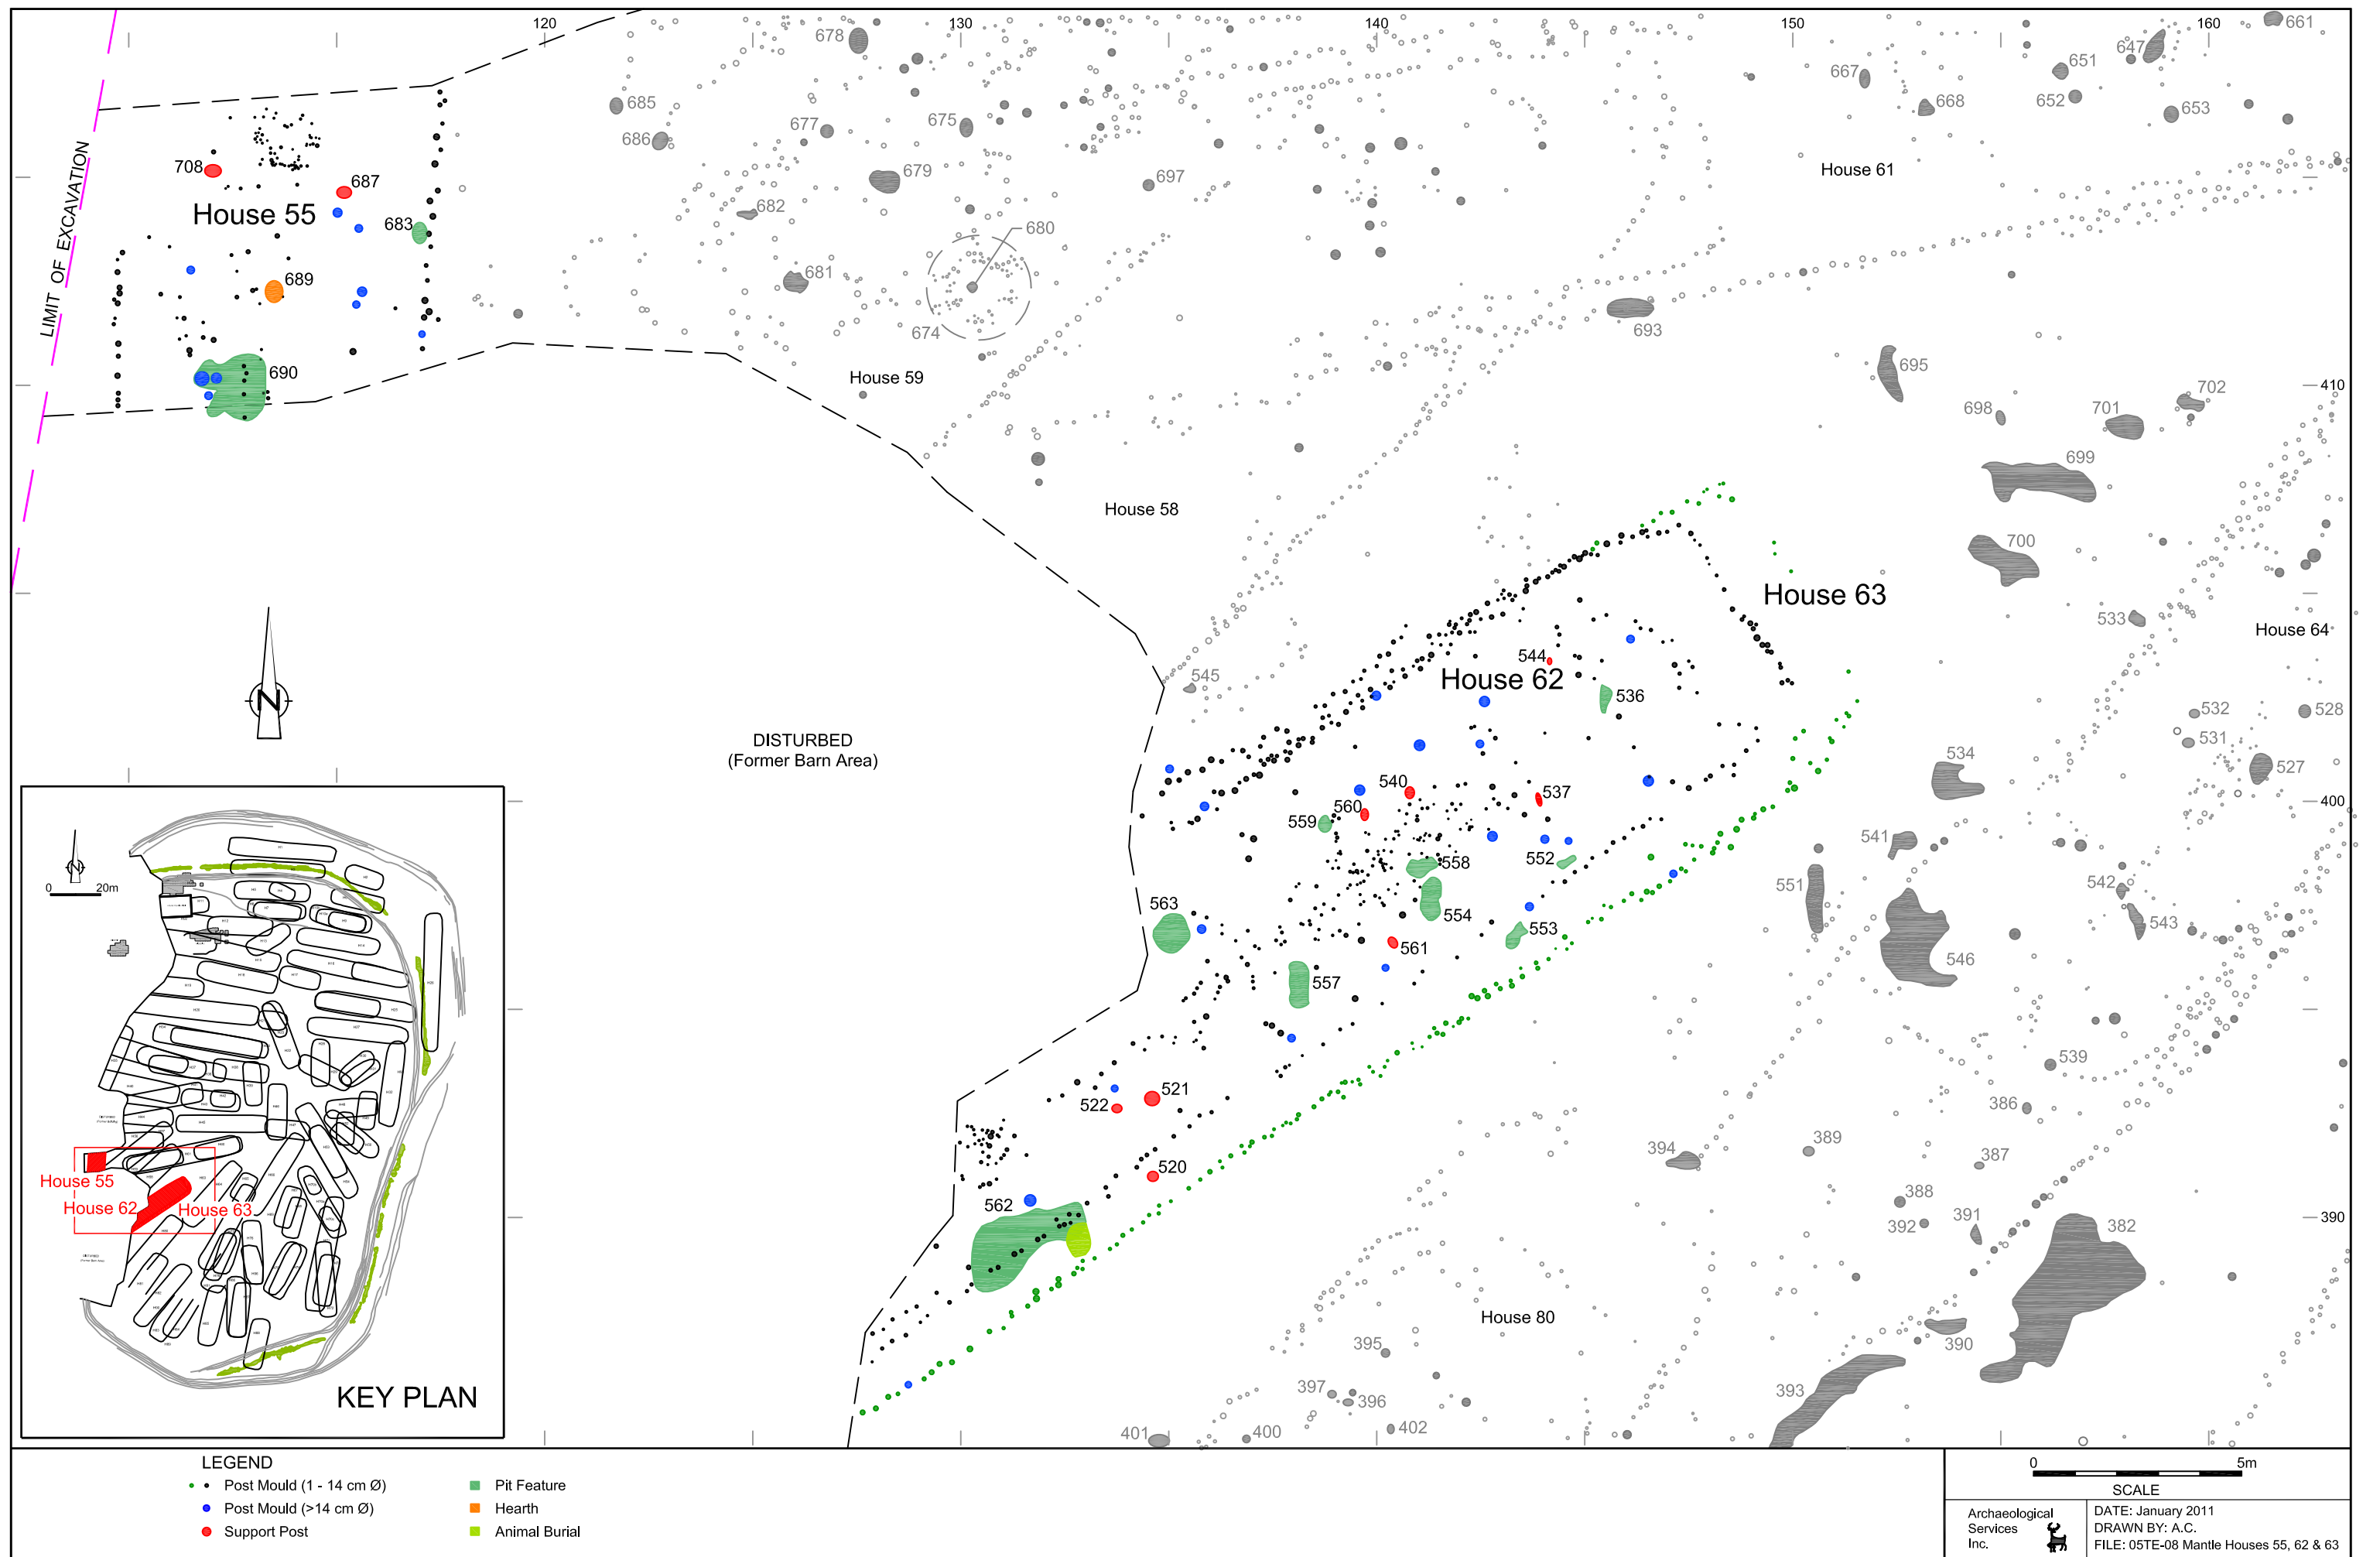

House 56 was another early occupation phase house located on the west side of the site perpendicular to the top of bank overlooking Stouffville Creek (Figure 5). The west portion of the house was completely disturbed by the construction of an outbuilding related to farm complex. The remaining visible eastern portion was 17.4 metres long and 6.4 metres wide, covering an area of 98 m<sup>2</sup> (Table 1). As with the other houses in this area of the site, the maximum length of the house was estimated by assuming that the west end was located at the top of the bank. Following this reasoning, the estimated maximum length of the house was 29 metres covering and its total area 182 m<sup>2</sup>.

The visible sections of the walls indicate that this house was constructed with posts placed in offset pairs along the south wall, while the north wall had a single row of posts (Figure 29). The average wall post density in these visible sections was 3.1 posts per metre. The east end of the house was squared off using a single row of posts. There was no opening for a doorway in the exposed end or wall sections. A line of posts that may have been part of a bunk line was found one metre north and parallel to the south wall of the house.

Several features were contained within this house. Only Feature 473 was located in an area not overlapping with House 57, but it was a recent animal burial related to the farm (Appendix B). The rest of the features and posts were either contemporary with House 56 or 57.

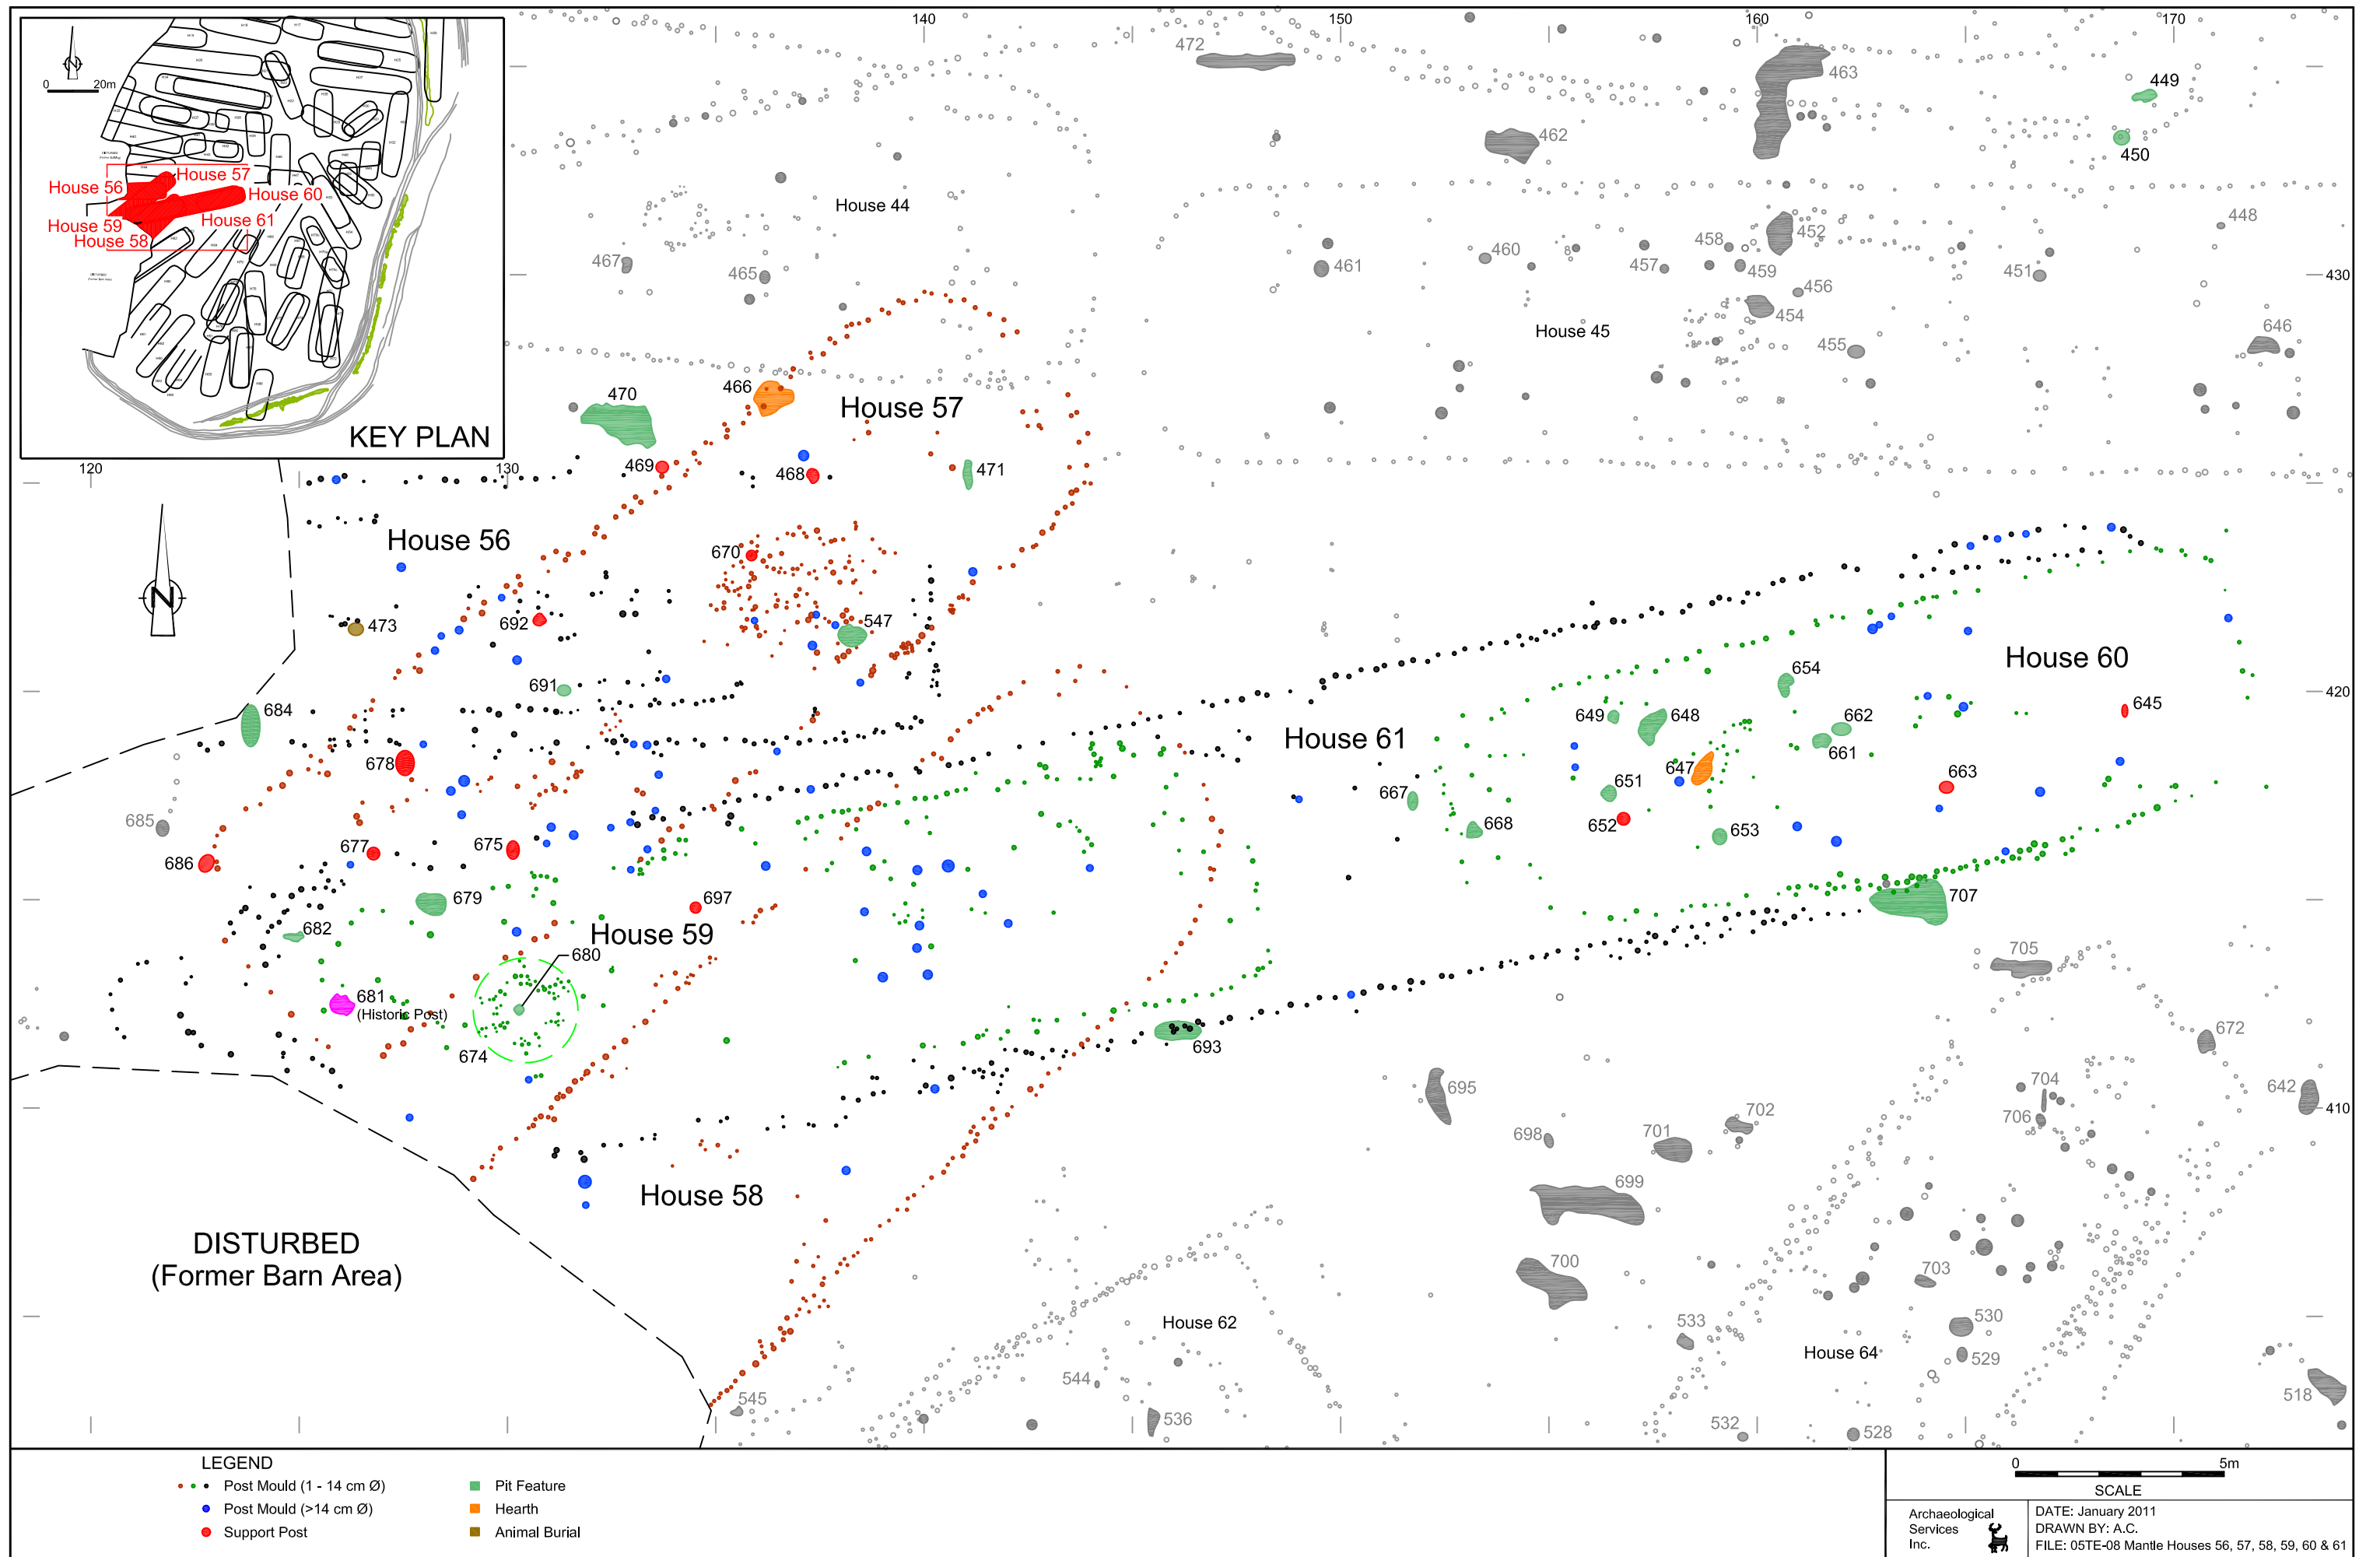

Figure 29: Plan View of Houses 56, 57, 58, 59, 60 and 61

### **House 57**

House 57 was located in the south half of the site on the west side, and it was likely part of the house group overlooking Stouffville Creek that included Houses 41, 45, 55 and 58 (Figure 5). It overlapped with portions of Houses 44 and 56, both of which were constructed during the early phase of village occupation, making this house part of the late phase of occupation (Figure 7).

The house was 23.6 metres long and 6.8 metres wide covering an area of 156 m<sup>2</sup> and oriented 53° east of north (Table 1). The wall posts were placed in pairs and in some sections of the walls additional posts were used for either strengthening or repair, resulting in an average wall post density of 5.0 posts per metre. The ends were slightly rounded in shape with a single row of posts used to close off the ends. There was an opening that measured 1.8 metres wide located in the northeast end of the house that likely served as a doorway. The other end was not well defined, and was probably located where the northwest wall curved inward to meet up with six posts (Figure 29).

There was a dense cluster of interior house posts located 5.6 metres from the northeast end. This cluster was composed of over one hundred posts in a random pattern that may have been the framework of an internal structure. Not all these posts would have been contemporary with each other, so it is likely that this structure was rebuilt several times. This house contained many large posts and support posts, possibly related to its construction late in the village's occupation when the slender saplings preferred for house construction likely became depleted in the vicinity of the village. Twelve of these posts were located within 1.5 metres of the side walls, and would have been used as internal framing for the house as well as support for bunk lines along both walls (Figure 29).

This house contained five pit features, seven support posts and one hearth. Only one feature (471) was found in an area that did not overlap another house and could be considered to be contemporary with this house (Appendix B). The hearth located in the alignment of the northwest wall likely pre-dates the house because posts from this wall were found in the fill of the hearth (Figure 29).

### **House 58**

House 58 was part of the aforementioned group of late phase houses located on the west side of the village (see House 57 description and Figure 5). The southwest portion of the house was disturbed by the construction of the barn and farm complex on the property. House 58 was almost parallel with House 57 and overlapped with the early phase Houses 59 and 61, which suggests that it was part of the late phase of village occupation (Figure 7).

The extant portion of House 58 was 19.1 metres long and 7.6 metres wide and covered an area 140 m<sup>2</sup> oriented 47° east of north (Table 1). It was not possible to measure the maximum length of the house because of the disturbance, but its length was estimated by extending the south wall of this house and the north wall of House 63. Since these two houses were likely contemporary with each other, they would not have overlapped. The maximum length of this house is estimated to have been 27 metres with an internal area of 202 m<sup>2</sup>.

The walls of this house were constructed by placing pairs of posts in a linear offset pattern (Figure 29). In some sections of the walls additional posts were used to strengthen or repair the structure, resulting in an average wall post density of 5.1 posts per metre. There was no internal post pattern revealing the presence of a bunk line. The northeast end was composed of posts placed in a semi-circular plan shape with a 1.2 metre wide doorway opening in the centre.

**House 59, 60 and 61**

These three houses were part of a sequence of construction that began in the early occupation phase (Figure 6), continued into the middle phase, and were replaced by Houses 57 and 58 during the late phase. House 59 and 60 were located in the south half of the village on the west side perpendicular to the slope overlooking Stouffville Creek (Figure 5). They were placed end to end similar to other early phase house pairs 44 and 45, 40 and 43, and 37 and 38. Houses 59 and 60 were later connected by new walls to form House 61 (Figure 29).

House 59 was 24 metres long and 6 metres wide; enclosing an area of 126 m<sup>2</sup> oriented 79° east of north (Table 1). Only a few sections of wall were visible, probably due to the disturbance caused by the construction of and activities in House 61. The walls that were visible had an average density of 3.3 wall posts per metre. Offset pairs of posts as well as single row posts were observed in the remaining wall sections. The east end was more rectangular and squared off in shape while the west end was rounder. Since the walls and ends of the house were disturbed, no clear doorway opening could be identified (Figure 29).

House 60 measured 19.2 metres long and 6.5 metres wide, covering an area of 124 m<sup>2</sup> and oriented 77° east of north (Table 1). This house was better defined than House 59. The walls were composed of post pairs offset from each other, while the ends had single row of posts. The average density of posts in this house was 2.7 posts per metre. There were additional posts along the south wall where the new south wall of House 61 joined it. The east end of this house was maintained as this house was connected with House 59 to create House 61 (Figure 29).

House 61 was truncated by the disturbance caused by the barn area on the west side of the village (Figure 29). The exposed portion of the house measured 47.4 metres in length and 7.6 metres in width. The total area enclosed by the exposed house was 360 m<sup>2</sup>. The west end of the house was not completely visible, but based on clusters of posts in this area the total estimated length of the house was 50 metres and the total area was 370 m<sup>2</sup> (Table 1).

House 61 was oriented 78 degrees east of north, similar to the orientation of Houses 59 and 60 (Table 1). House 61 postdates Houses 59 and 60, but pre-dates Houses 57 and 58. As outlined above, this house was created by connecting Houses 59 and 60 with newly constructed sidewalls extending from the west end of House 59 to the east end of House 60. The south wall of House 61 was offset 0.8 metres from the south wall of House 59, and it then continued east to merge with the south wall of House 60. The north wall of this house was parallel to the walls of 59 and 60 and offset from those walls by 0.7 metres and 1.2 metres, respectively. This north wall was tapered at the east end to intersect with the north wall of House 60 (Figure 29). The average wall post density of House 61 was 3.6 posts per metre.

Twelve pit features and five support posts were contained within the footprint of these three houses (Appendix B). The majority of them were found in the House 60 area in the east half of House 61. Only pit feature 667 was found in an area of House 61 that was not previously within either House 59 or 60. One hearth was contained within these houses. It was located on the central axis of House 60 or House 61. It is unclear to which of these two houses this hearth belongs. A circular cluster of posts (Feature 674) was found toward the east end of House 59 or House 61. The cluster was likely the place for an internal house structure such as rack or an above ground sweat lodge. Due to its location, it was not possible to directly associate this feature with either House 59 or 61 (Figure 29).

House 61 was probably constructed during the middle transitional phase of the site, but it was still part of the settlement of the village established during the early phase. This was the only example on the site of two houses being combined into a single larger one.

## **Houses 62 and 63**

Houses 62 and 63 were located in the southwest area of the village, oriented perpendicular to the slope (Figure 5). These two houses were part of the southern group of early phase houses that were rotated to remain perpendicular with the gentle slope of the land (Figure 6). House 62 was built in the early phase, and House 63 was constructed later on the same spot. One or the other probably stood here for the entire duration of the village's occupation.

The southwest portions of these houses were disturbed by the construction of the barn that was part of the farm complex, so it was not possible to measure the maximum length of each house. House 62 was estimated to be 31 metres long with an area of 202 m<sup>2</sup> and House 63 was estimated at 33 metres long with an area of 250 m<sup>2</sup> (Table 1).

House 62 was the narrower of the two houses (6.3 metres wide), and the length of the south wall was 27.2 metres. The exposed area of the house was 129 m<sup>2</sup> oriented 56° east of north (Table 1). The south wall was made up of posts placed in a single row while the north wall contained more posts than the south wall, arranged in a linear cluster. The additional posts in the north wall would also have been associated and overlapping with the north wall of House 63. The north wall was tapered and a single row of posts was used to form a squared off end to the house. The average density of posts in the house walls was 3.5 posts per metre. A 1.3 metre wide opening was found at the intersection of the south wall and the end. This opening probably served as a doorway with the interior posts creating an internal barrier to isolate the door from the rest of the house (Figure 28).

House 63 was built directly over the footprint of House 62. It was oriented 56° east of north, the same as the earlier house, and shared the same alignment of the north wall. This house was 7.6 metres wide and the exposed length of the south wall was 29.9 metres, with a total exposed area of 176 m<sup>2</sup> (Table 1). The south wall was comprised of posts placed in pairs and offset from each other. Additional posts were also used in the wall for extra support and/or repairs, with a high average density of wall posts (6 posts per metre). The pattern of posts in the north wall was unclear because of the shared alignment of the houses. There was evidence for the presence of a bunk line: several large posts formed a line 1.4 metres from the south wall, and another formed a line 1.7 metres from the north wall (Figure 28).

Nine pit features and eight support posts, as well as several other large posts, were contained within the footprint of these two houses (Appendix B). Only Feature 553 and Support Post 520 were located outside of House 62, so they were likely contemporary with House 63. Feature 562, a pit feature located on the south wall of House 62, would have been associated with House 63 (Figure 28). The posts for that wall were found below the feature fill, which suggests that the feature post-dates House 62. It is therefore likely that House 63 post-dates House 62.

## **House 64**

House 64 was built in the early phase of the occupation and was extended twice, remaining in place into the late phase (Figures 6 and 7). It was probably occupied throughout the duration of the village's occupation. It was located in the central area of the southern half of the site (Figure 5). House 65, a late phase house, was built 0.8 metres east of the earliest part of House 64, and House 79 was also constructed 3.5 metres east of House 64. The northernmost portion of this house was built earliest, with the extensions lengthening the house to the southwest.

House 64 was originally 18.4 metres long and 5.9 metres wide, enclosing an area 109 m<sup>2</sup> oriented 38° east of north (Table 1). The shape of this house was rectangular with tapered ends. The walls were constructed using posts placed in a single row, and the north end was created using a single row of posts with no opening for a doorway. There was a 1.2 metre wide doorway opening in the west wall near the north end.

Large interior posts in two rows parallel to the east and west walls may have been the supporting framework for bunk lines. The majority of the features contained within this house were located in the northern portion, which was constructed first and occupied the longest (Figure 30).

The house was first extended 5.6 metres to the south where a row of posts was found forming the second south end. As the house was extended over time the north end was maintained. The second version of this house was 24 metres long, and the east wall of the initial house was extended along the same alignment to connect with the new south end (Figure 30). The north wall was doubled in thickness resulting in a house width of 7.2 metres (an increase of 1.3 metres). In this second construction stage the total enclosed area of the house was increased to 160 m<sup>2</sup> (Table 1). Two pit features were contained within the new extended portion (Appendix B).

House 64 was extended once more to its maximum length of 31 metres, possibly during the late occupation phase (Table 1 and Figure 7). The new portion was constructed by building a new east wall and extending the west wall. The construction of the new walls and extension increased the width of the house to a maximum of 7.9 metres and its enclosed area to 219 m<sup>2</sup>. The south end was slightly curved in shape and formed using only five or six posts. Since so few posts were used to close off the south end of the house, it was not possible to identify an opening for a doorway (Figure 30). Only one additional pit feature was located in this last extension of the house.

As House 64 was extended over time, the bunk lines along the east and west walls were extended as well. There was a distinct line of large posts and support posts located parallel and offset 1.4 metres from the east wall. Fewer large posts and support posts were used for the west wall bunk line with a support post (Feature 389) located at the south end of that bunk line. As a result of these multiple extensions and rebuilding episodes, this house had the second highest wall post density in the village (7.6 posts per metre) (Table 1).

A total of ten pit features and nine support posts as well as other large posts was contained within this house (Appendix B). Since the house was extended, the features within the first construction of the house could be contemporary with any of the three stages.

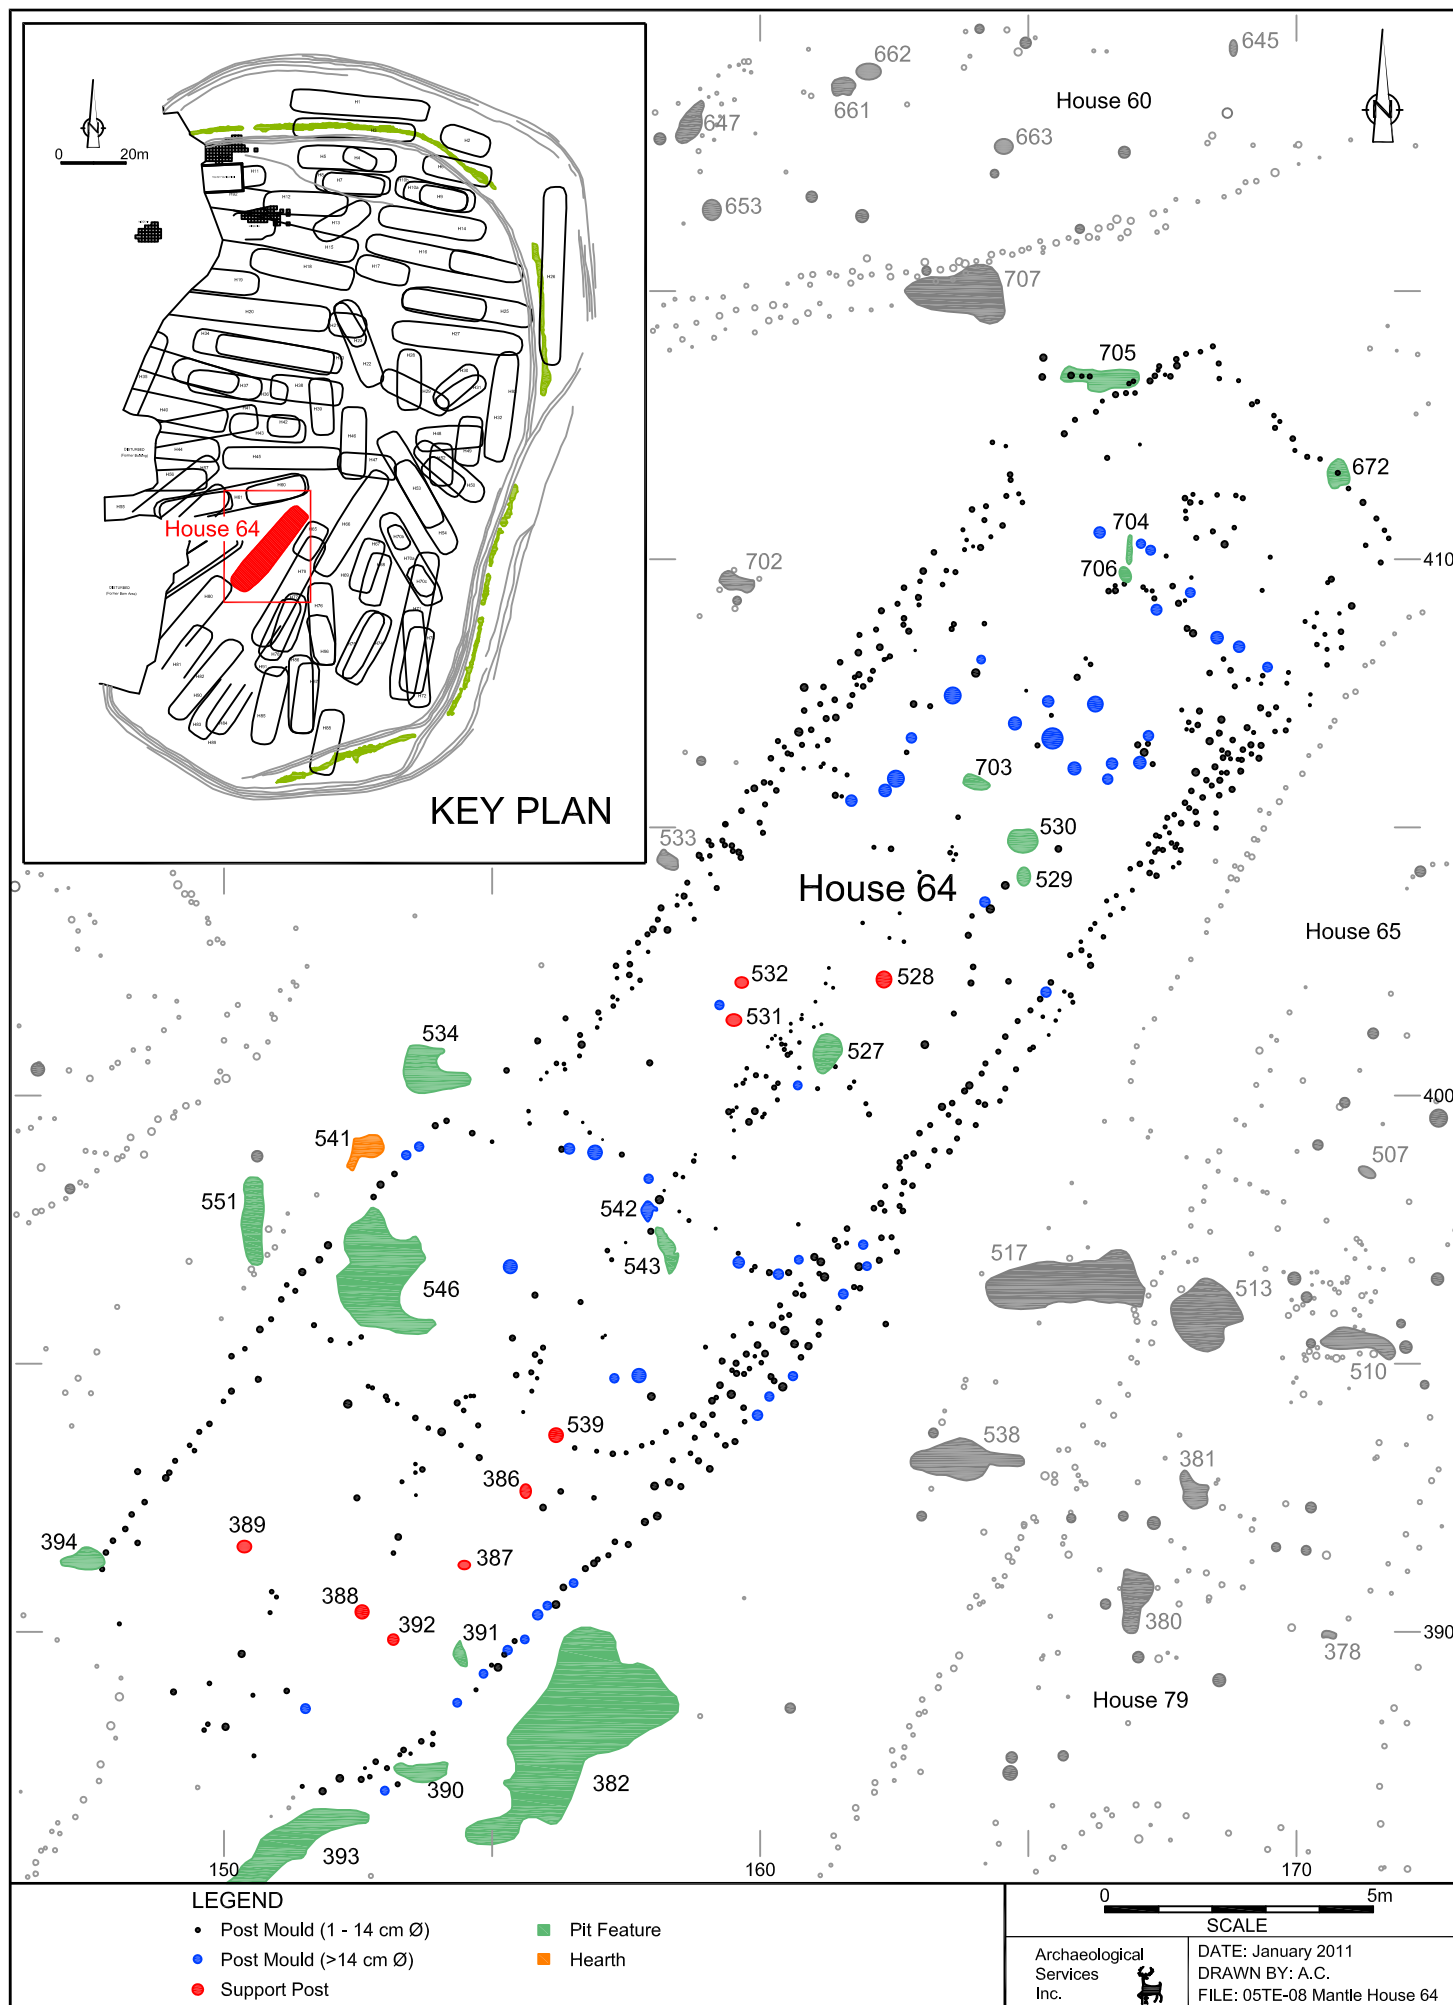

Figure 30: Plan View of House 64

### **House 65**

House 65 was a small structure located between Houses 64 and 66 (Figure 5). It measured 11.7 metres long and 7.1 metres wide, making it the second shortest house at the site after House 42 (Table 1). It overlapped House 79, which is associated with the early phase of occupation, suggesting a late occupation for House 65 (Figure 7). This house enclosed an area of 79 m<sup>2</sup> and was oriented 32° east of north, mirroring the orientation of House 66 immediately to the east.

The shape of this house was rectangular with posts placed in a single row to form the walls and ends. The wall post density was 3.8 posts per metre and an opening 1.3 metres wide was found in the northwest corner of the house. Only one pit feature was identified within House 65, but its association is unclear since it was located in the area overlapping with House 78 (Figure 31). Due to the close proximity and parallel orientation of Houses 64, 65 and 66, these three houses could represent an associated group of late phase structures within the village. The relative paucity of features and posts in House 65 compared to Houses 64 and 66 might indicate that this was a semi-permanent or special purpose structure related to or utilized by the other houses.

### **House 66**

This house measured 35 metres in length and 7.4 metres in width, enclosing an area of 253 m<sup>2</sup> and oriented 32° east of north (Table 1). It was located in the south half of the site within the central area surrounded by House 46, 54, 65, 68 and 70, and may have been part of the late phase group including Houses 64 and 65 (Figure 7). It overlapped with House 69, which was probably an early occupation phase house.

The posts used to construct the walls of this house were placed in offset pairs in some sections and a single row in others, for a total average wall post density of 3.9 posts per metre. The walls at the north end were slightly tapered with a straight single row of posts used to close off the end. Several larger posts were found in the west wall at the north end that may have been used for strengthening or repairing that section of the wall. The south end was only defined by the tapering of the house walls; no posts were in place to close off the end. There was a 3.2 metre wide opening with a post in the centre of the east wall, and a 1.6 metre wide opening in the south half of the west wall. These could have been the doorways leading into the house. The doorway in the west wall of this house was located adjacent to the north end of House 65, which may indicate a connection between the two houses. In the south half of the house along the west wall was a single row of interior posts 1.5 metres from the wall that were likely part of a bunk line. There was a similar line of large posts parallel to and 1.3 metres from the east wall (Figure 31).

Many features were contained in this house, including fourteen pit features, seven support posts and a midden-like feature located at the south end (Appendix B). There were two separate concentrations of interior post clusters eleven metres apart and found along the central axis of the house. These concentrations could have been from structures such as racks placed in cooking areas, but no hearth features were found associated with these posts (Figure 31).

### **House 67**

House 67 was part of the late phase group of houses discussed above. It was located 2.6 metres east of House 66 and 1.1 metres west of House 70a (Figure 5). This house measured 16.7 metres long and 7.1 metres wide, covering an area of 118 m<sup>2</sup> and oriented 19° east of north (Table 1).

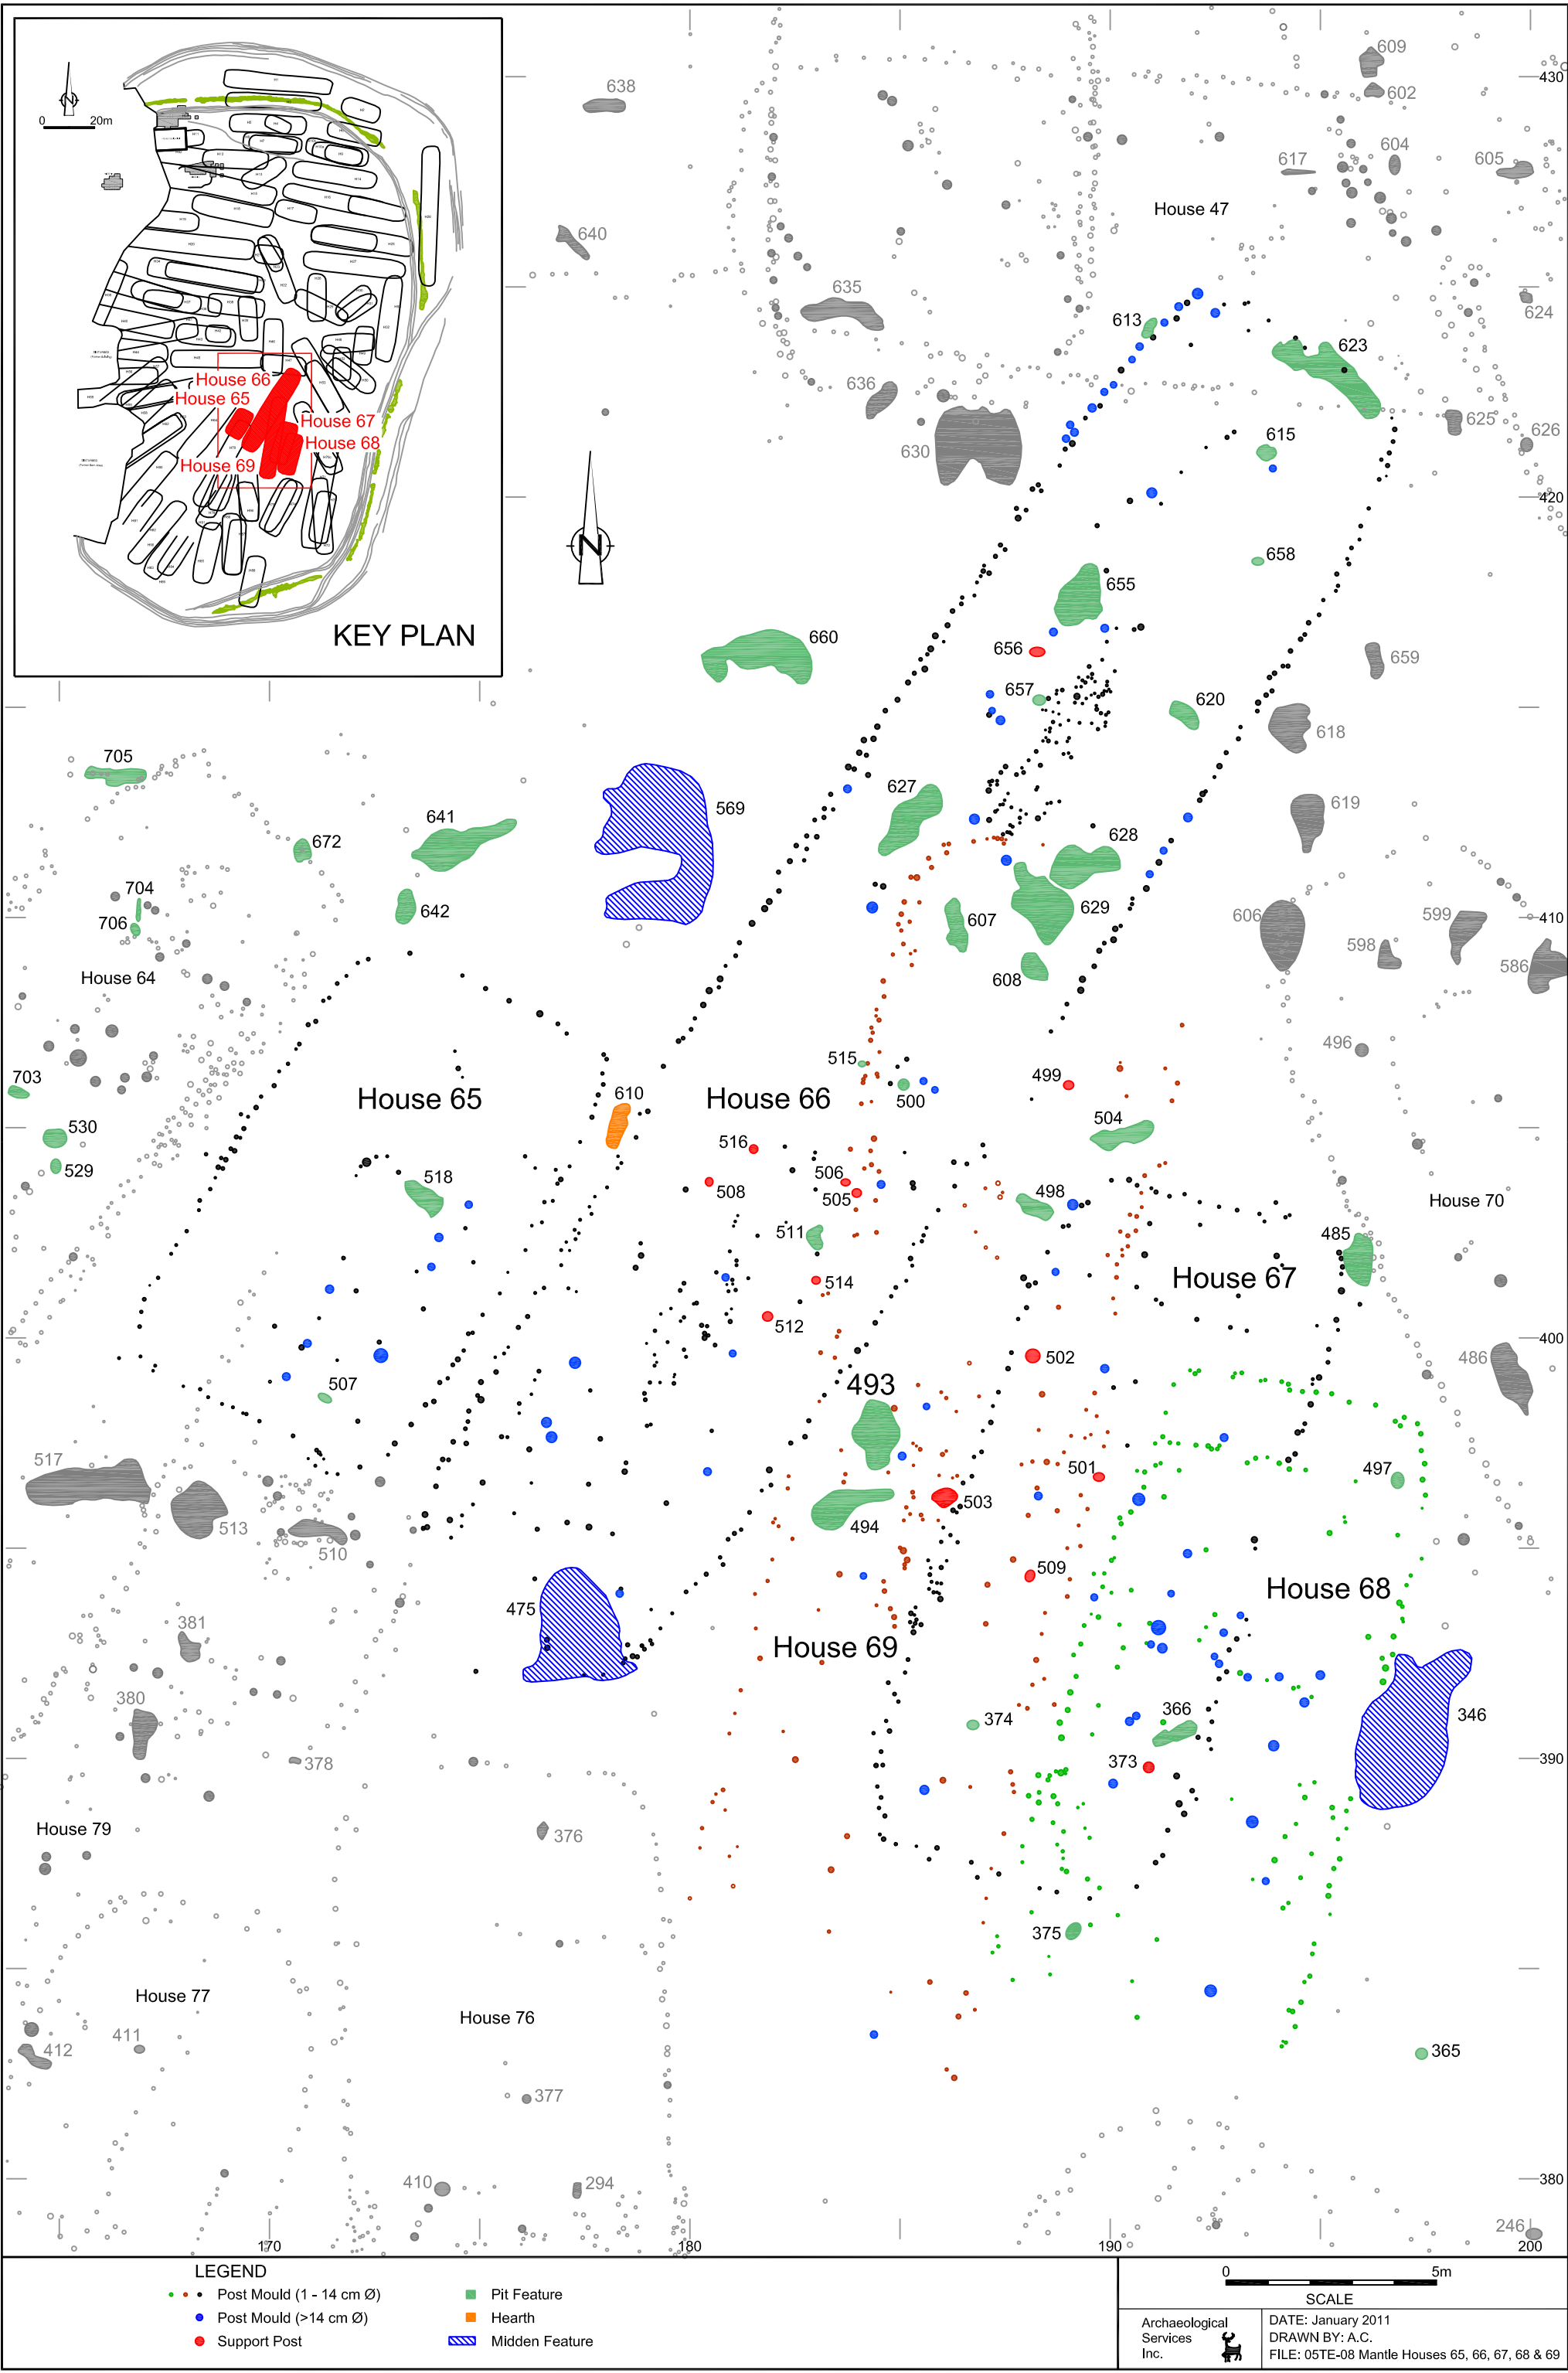

Figure 31: Plan View of Houses 65, 66, 67, 68 and 69

The walls were generally composed of posts placed in a single row, but some offset post pairs were used at the south end of the west wall. The average wall post density was 3.0 posts per metre. The sides were tapered at both ends with single rows of posts set in place to close off the ends. The plan of the house was rectangular with slightly rounded corners. There was a 3.7 metre wide doorway opening located in the middle of the east wall that seemed to be the only entrance into the house. This doorway was configured similarly to the east wall doorway in House 66. Both openings were over three metres wide and had a single post located in the centre (Figure 31).

There was one pit feature contained within the walls of this house (Appendix B). It was located in the southeast quadrant of the house in an area that overlapped with House 68, so it could not be directly associated with either house. Feature 485, an exterior feature, was located between the northeast corner of the house and the west wall of House 70a. The size of the feature was limited by its proximity to both houses, which suggests that Houses 67 and 70a were contemporary with each other (Figure 31).

### **House 68**

Houses 68 and 69 were likely the predecessors to House 67 (Figure 6). The three were approximately the same size and oriented roughly parallel to each other. House 68 was 15.5 metres long and 7 metres wide, enclosing an area of 105 m<sup>2</sup> and oriented 18° east of north (Table 1). This house was part of the early occupation development in the south half of the village. Houses in this half were oriented approximately north-south in order to remain perpendicular to the topography of the immediate area (Figure 6).

The wall posts were generally placed in a single row, with pairs of posts in some sections. The average wall post density was 2.8 posts per metre. A partial row of interior posts crossing the house was located 1.8 metres from the north end. The function of this interior wall is unclear, but it may have been used to isolate the north end of the house as a storage area. The south end of the house was closed off using a couple of posts situated between the ends of the side walls, while the north end was framed with a complete single row of posts. There was a 2.8 metre wide opening in the east wall that may have been a doorway, but it is perhaps more likely that these posts were erased by a later, midden-like feature located in the opening. A row of nine large posts was observed 1.6 metres from and parallel to the west wall, while another row of five large posts was found 1.7 metres from the east wall. Both of these rows were likely part of the framework for bunk lines running along each wall (Figure 31).

Three pit features were found within the footprint of this house (Appendix B). Feature 366 was located in the area common to both Houses 68 and 67, so its association is unclear, while Features 375 and 497 were only within House 68.

### **House 69**

House 69 was part of the early phase of the village's occupation, and may have been replaced by House 67 (Figure 6). Its exposed length was 24.4 metres and its total length was estimated at 27 metres based on its proximity to the early phase House 76 to the southwest. It was 6.9 metres wide and enclosed a total area of 187 m<sup>2</sup> oriented 11° east of north (Table 1). It was located 1.1 metres west of House 68, and portions of House 69 overlapped with Houses 66 and 67, both late phase houses.

The walls were made up of posts placed in single and paired rows with some clustering. House 69 had been disturbed by the construction and occupation of Houses 66 and 67, resulting in the loss of sections of the house. The average wall post density for the well-preserved north-western section of wall was 3.5 posts per metre. The location of the north end was defined by the inward curving of the west wall, while the location of the south end could only be estimated based on the endpoints of the side walls (Figure 31).

There were a total of nine pit features and five support posts found in the footprint of this house (Appendix B). Only four of those features and one support post were in areas solely occupied by this house.

Houses 68 and 69 were both designated as early phase houses because they overlapped with late phase Houses 66 and 67 (Figures 6 and 7). They were part of the early construction phase along the south perimeter of the open area in the central portion of the site.

### **Houses 70a, 70b and 70c**

Houses 70a, 70b and 70c were located in the south half of the site. House 70a encompasses two smaller houses, with House 70b being the northernmost and House 70c being the southernmost (Figure 27). Based on their shared alignment with Houses 53 and 54, and since they overlap with early phase House 71, these houses are placed in the mid-late phase of village occupation with House 70a belonging solely to the late phase of village occupation (Figure 7).

House 70b was 8.1 metres in length, 4.7 metres in width, and encompassed an area of 35.6 m<sup>2</sup>. House 70c was 10.4 metres long and 5.7 metres wide, encompassing an area of 53.5 m<sup>2</sup> (Table 1). The footprints of both of these houses were disturbed by construction of and activities in the later House 70a. This made it impossible to accurately estimate wall post density for the smaller houses. House 70a may have been built to replace and/or join together Houses 70b and 70c, as was the case with Houses 59, 60 and 61 (see above). The remaining wall posts visible in Houses 70b and 70c are arranged in a combination of single and paired posts. The north end of House 70b appears to have been rounded (Figure 27).

House 70a measured 31.5 metres in length and 7.6 metres in width, enclosing an area of 222 m<sup>2</sup>. All three of these houses shared an orientation of 150° east of north (Table 1). Houses 70a and 70c were located 7.6 metres west of the late phase inner palisade. The east wall of House 70a was located 5.1 metres southwest of Houses 53 and 54 (Figure 5).

The wall posts of House 70a were placed in pairs offset from each other, except near the ends where single rows of posts were used. The average wall post density in this house was 4.2 posts per metre (Table 1). The ends of the walls were tapered with a single row of posts used to close off both ends. A 1.2 metre wide opening that may have served as a doorway was found in the middle of the north end and another opening that was 2.2 metres wide was identified in the middle of the west wall. This wider doorway was similar to the east doorway of House 67; except that this opening had two posts in the middle while the doorway in House 67 only had one (see Figure 31). An interior row of posts partially crossing the width of the house at the north end could have been placed there to separate the north entrance from the rest of the house, providing protection from the outside elements for the inhabitants. Several large posts formed lines parallel to the walls and were likely part of the internal framing of the house as well as support for the bunk lines located along the inside of both walls. The west bunk line was approximately 1.5 metres wide and the east one was 1.8 metres. Single rows of interior posts were located within 0.6 metres of the house walls (Figure 27). These extra post rows were likely used as support for the middle section of the side walls.

These houses contained several features and support posts (Appendix B). Seventeen pit features, eleven support posts and one ash pit along with many other large posts were found in the footprint of these houses. Nine of those pit features and six support were located in the area overlapping with House 71, so they could not be directly associated with any house.

The southern portion of House 70a and most of House 70c overlapped with House 71. The latter house is associated with the early occupation of the village, which means that these are late phase houses (Figure 7). Houses 70b and 70c may be mid-late phase houses.

### **House 71**

House 71 was the easternmost house in the southern half of the village assigned to the early phase of occupation (Figure 6). Part of the north half of this house overlapped with House 70, meaning that any features and posts in this area could not be associated with one or the other. This house also overlapped Houses 72 and 73, as did House 70 (Figure 5).

House 71 was 46.3 metres long and 7.7 metres wide making it the fifth-longest house at the site. It enclosed an area of 367 m<sup>2</sup> and was oriented 11° east of north (Table 1). The walls were constructed using posts placed in pairs offset from each other with an average density of 4.0 posts per metre of wall. The ends of the walls were tapered and squared off with a single row of posts used to close off the south end and a clustering of posts in the north. Two doorway openings were found leading into this house: one was a 1.4 metre wide opening in the south end; and the other was a 1.8 metre wide opening in the middle section of the west wall. There were two partial interior rows of posts parallel with the walls of the house. Those rows, combined with larger posts near the walls, would have supported two bunk lines that were each one metre wide (Figure 32).

The midden-like feature (238) located on the west wall post-dates the house because posts for this wall were found in the subsoil below the feature but not within the feature fill. Feature 238 was therefore be contemporary with late phase of the site's occupation (Appendix B).

Twenty pit features, four hearths, three ash pits and eleven support posts were contained within this house. Of those twenty pit features, only seven were in areas of the house that did not overlap with another. The four hearths were located on or near the central axis of the house, and, given the pattern of hearths being placed away from house ends or walls at Iroquoian sites (Finlayson 1985), these four were likely associated with House 71 and not the other two overlapping houses. The three ash pits would have been associated with the hearths in House 71 as well (Figure 32).

House 71 was the first house built in the construction sequence that included Houses 72 and 73. It probably was occupied for a long time before one of the others were built, and may have stood from the early phase into the middle transitional phase. It was eventually replaced by House 72, which was later replaced by House 73 around the time that House 70 was built (Figure 32).

### **House 72**

House 72 was the intermediate house in the construction sequence involving Houses 71, 72 and 73. The south end of this house was within 0.5 metres of the late phase palisade (Figure 5). No late phase houses are built as close to the late palisade as this one, so House 72 was probably contemporary with the early phase palisade located thirteen metres to the east. As such, it has been assigned to the early to middle phase of village occupation (Figure 6).

This house was 30.3 metres long and 7.1 metres wide, covering an area of 192 m<sup>2</sup> and oriented 357° east of north (Table 1). Wall post density averaged 4.1 wall posts per metre, but there was no consistent pattern of wall posts throughout the house. The east wall was mainly composed of a single row of posts, while the west wall was made of offset post pairs and clusters. The middle section of the west wall had several additional posts that may have been related to wall repair or strengthening. The south end was essentially semi-circular in shape with a 1.4 metre wide opening for a doorway located in the centre.

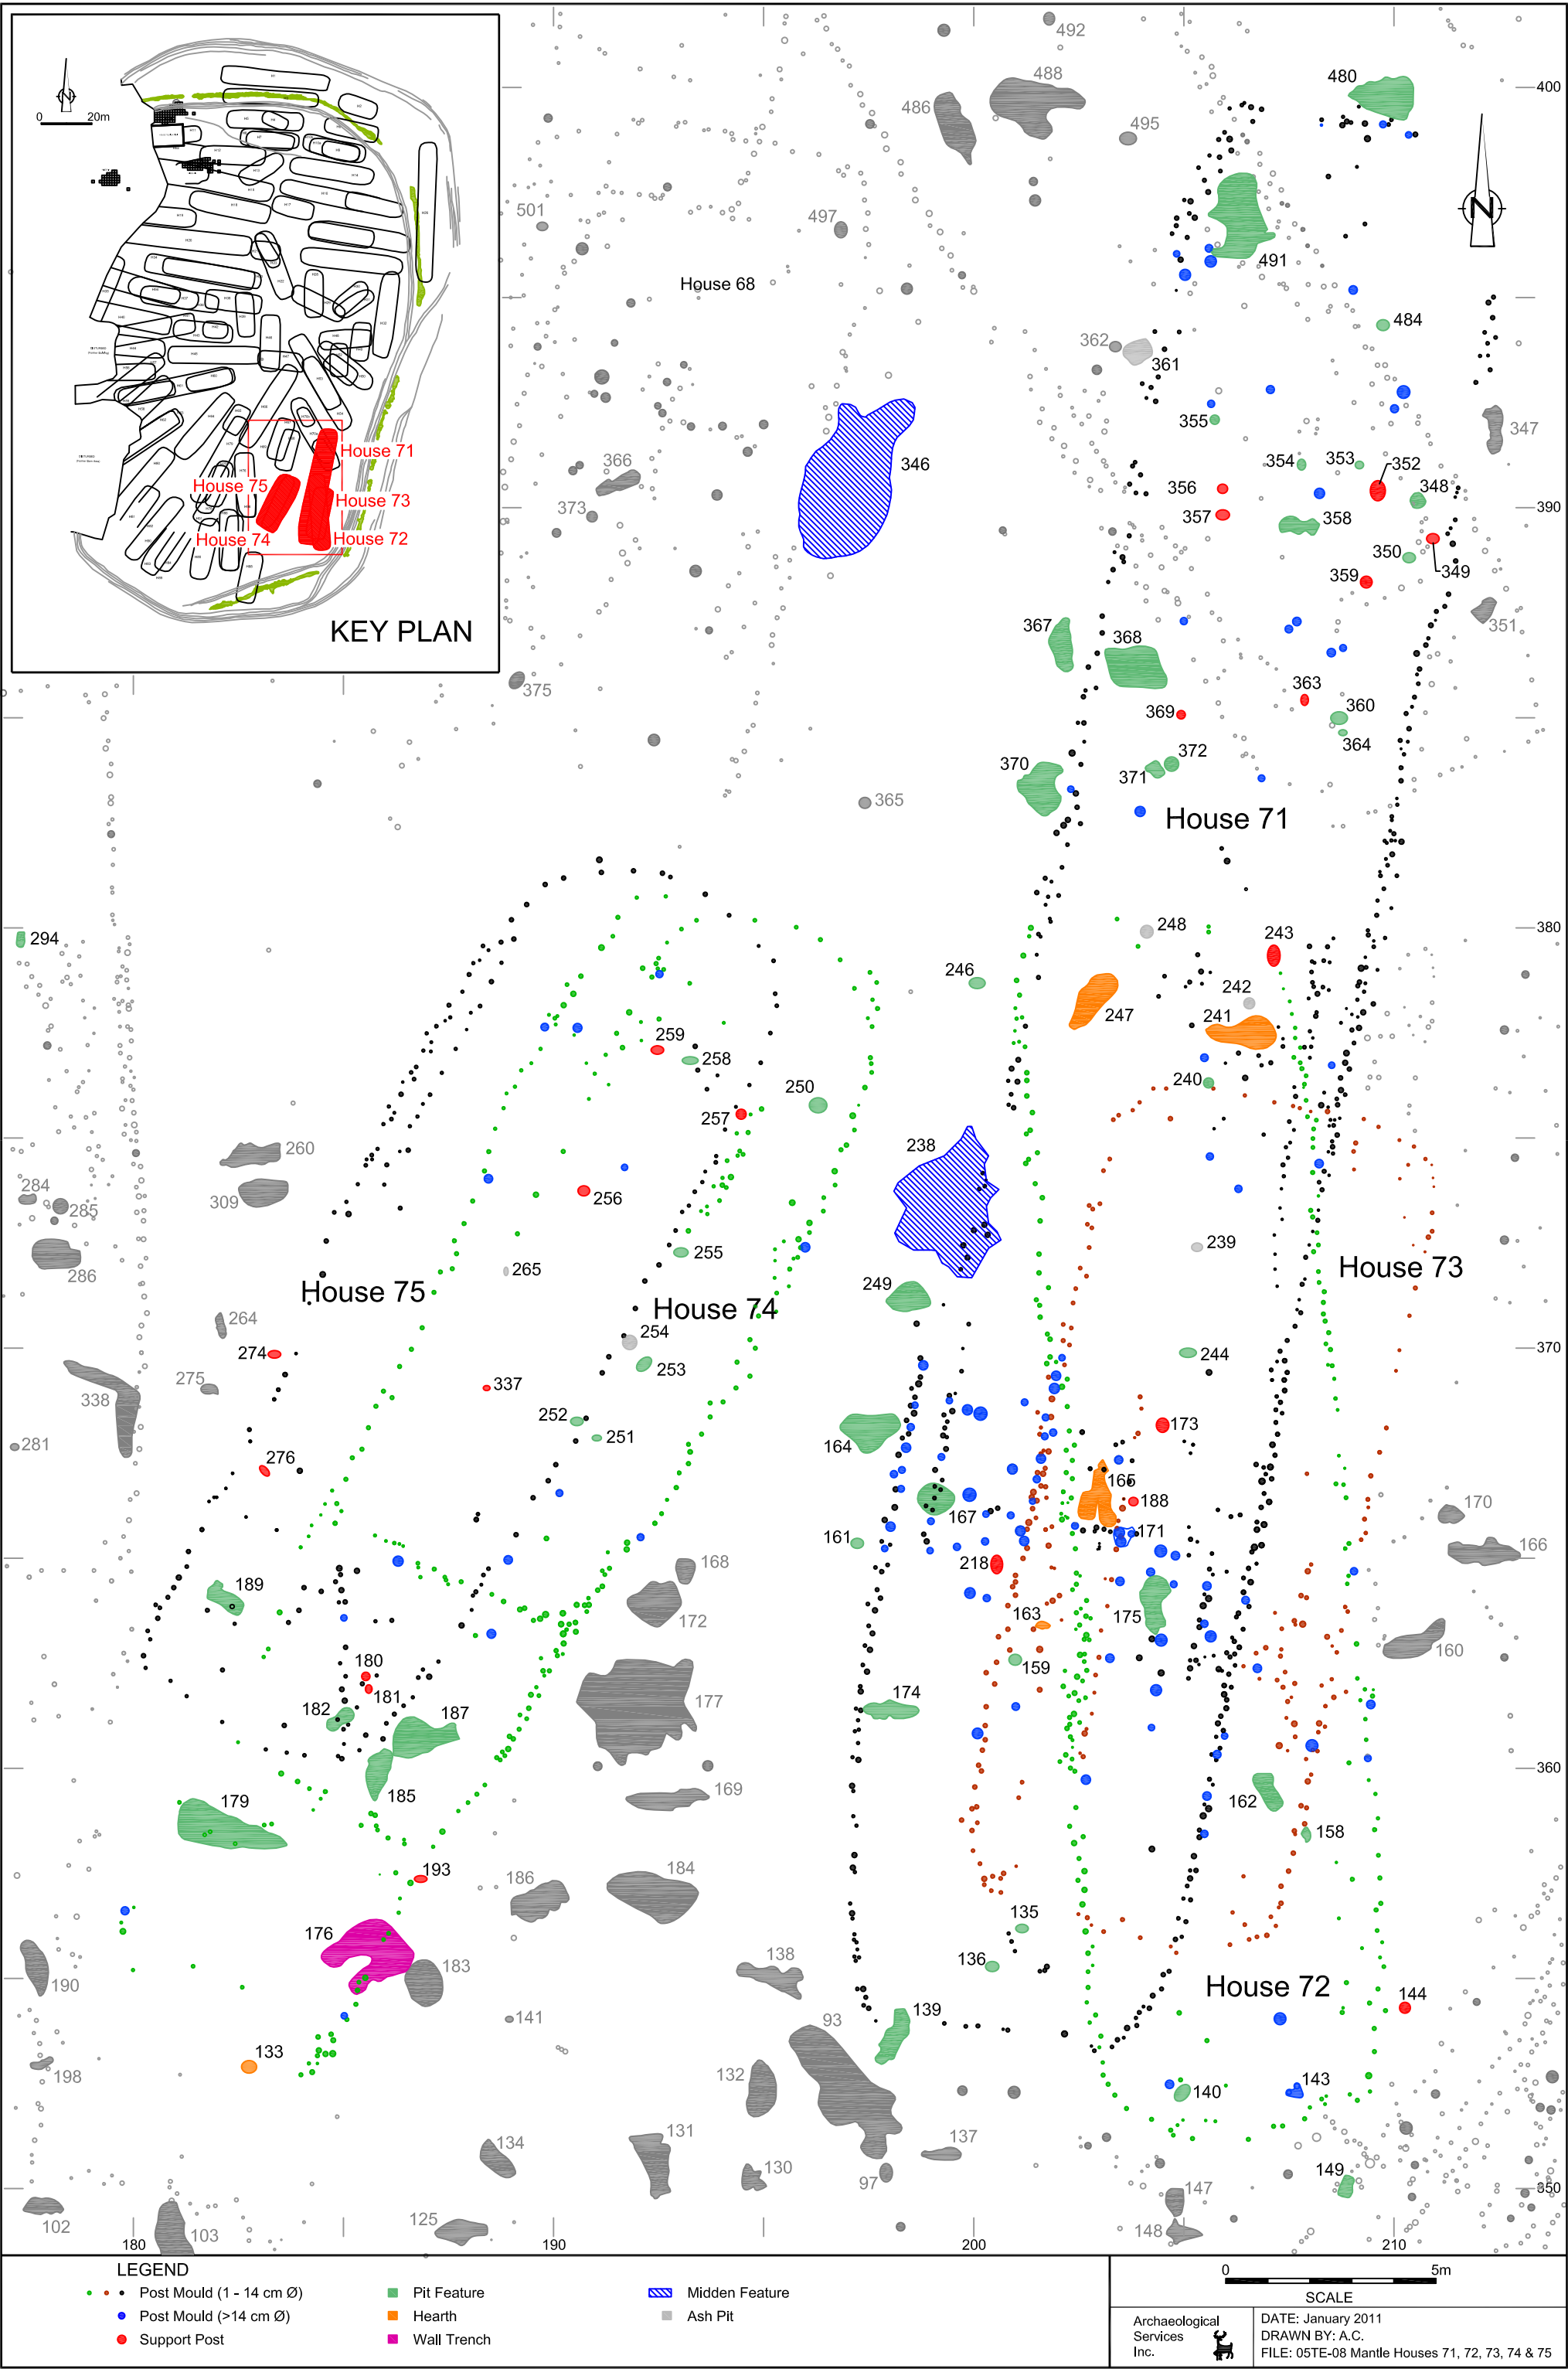

Figure 32: Plan View of Houses 71, 72, 73, 74 and 75

There were no posts across the north end of the house. This end was defined by the tapering of the sidewalls (Figure 32).

House 72 overlapped with portions of Houses 71 and 73, so many of the features contained within the footprint of this house may be associated with one of the other two houses. Only Features 140, 143 and 158 were located within an area solely within the footprint of House 72 (Appendix B).

House 72 post-dates House 71 and pre-dates House 73. This house may have only been occupied for a short time before House 73 was constructed along the inner palisade built in the late phase of the village.

### **House 73**

House 73 was the final house constructed in the sequence of houses involving Houses 71, 72 and 73 (Figure 5). This house was 20.1 metres long and 8.0 metres wide, enclosing an area of 152 m<sup>2</sup> and oriented 13° east of north (Table 1).

As with House 72, this house had single post rows along with offset post pairs. The east wall had a single row while the west wall had post pairs, and the average density of both walls was 3.3 posts per metre. The ends were clearly defined with the sidewalls curved inward and a single row of posts used to close off the ends. There was a 1.9 metre wide doorway opening on the west side of the south end and a 1.4 metre wide opening in the east wall near the north end (Figure 32).

There were no features solely associated with House 73. Feature 175 was situated along the central axis of this house and surrounded by large posts, and may have been focus of a food preparation activity (Figure 32).

This house was the last one standing of the three constructed in the southeast corner of the site. It was contemporary with the inner late phase palisade and may have been contemporary with House 74, which was located 6.5 metres to the west and shared the same orientation as this house (Figure 7).

### **Houses 74 and 75**

These two houses were constructed on nearly the same location and oriented similarly (Figure 5). House 74 was 23.6 metres long and 7.6 metres wide, covering an area of 160 m<sup>2</sup> and oriented 28° east of north. House 75 was slightly shorter, measuring 23.2 metres long and 7.1 metres wide. It covered an area of 148 m<sup>2</sup> oriented 27° east of north (Table 1).

House 74 was located 6.5 metres west of House 73 and 3.6 metres east of House 76 (both late phase houses). The walls were constructed by placing posts in a single row or in pairs, with an average wall post density of 3.4 posts per metre. There was a single post row crossing the house that was probably the original south end of the house or perhaps an interior dividing wall. If this wall was the original south end of the house, then the house was initially 17.5 metres long and enclosed an area of 120 m<sup>2</sup> (Table 1) There was a concentration of posts at the east side of this possible end where it connected with the east wall of the house. The additional posts provided support for the wall as it was extended south. If this crossing wall was a dividing wall, then the one metre wide opening that was found at the west end of this wall may have been the doorway to pass into the different areas of the house (Figure 32).

The north end was semi-circular in shape with a single row of posts used to form the end, while the south ends were both squared off and flatter. There was a possible bunk line section starting at the north end of the west wall and extending south to the middle of that wall. This was indicated by the presence of a row of posts approximately 1.4 metres from the west wall (Figure 32).

House 75 was constructed using posts placed in a single row pattern to form the walls and ends. There was no indication that this house was extended, as may have been the case with House 74. The average wall post density was also somewhat lower at 2.8 posts per metre, but there is a doubling of the north end of the west wall that suggests that that wall section was completely rebuilt. The footprint of this house was the same as House 74 with a rounded north end and a squared off south end (Figure 32). This similar plan supports the suggestion that one house was built to replace the other.

Ten pit features, seven support posts, two ash pits and several large posts were found contained within these two houses (Appendix B). Two of those pit features, five support posts and one ash pit were found in the area shared by both houses so it is unlikely they can be associated with either house.

We cannot be certain which house was built first. It may be that House 75 was earlier because of its close proximity to House 76, which was occupied in the late phase of occupation (Figures 6 and 7). They are less than a metre apart, whereas House 74 was 4.2 metres from House 76. Even though the late phase settlement pattern of the village appears to have been more random, there was usually a minimum separation of one metre between houses.

### **House 76**

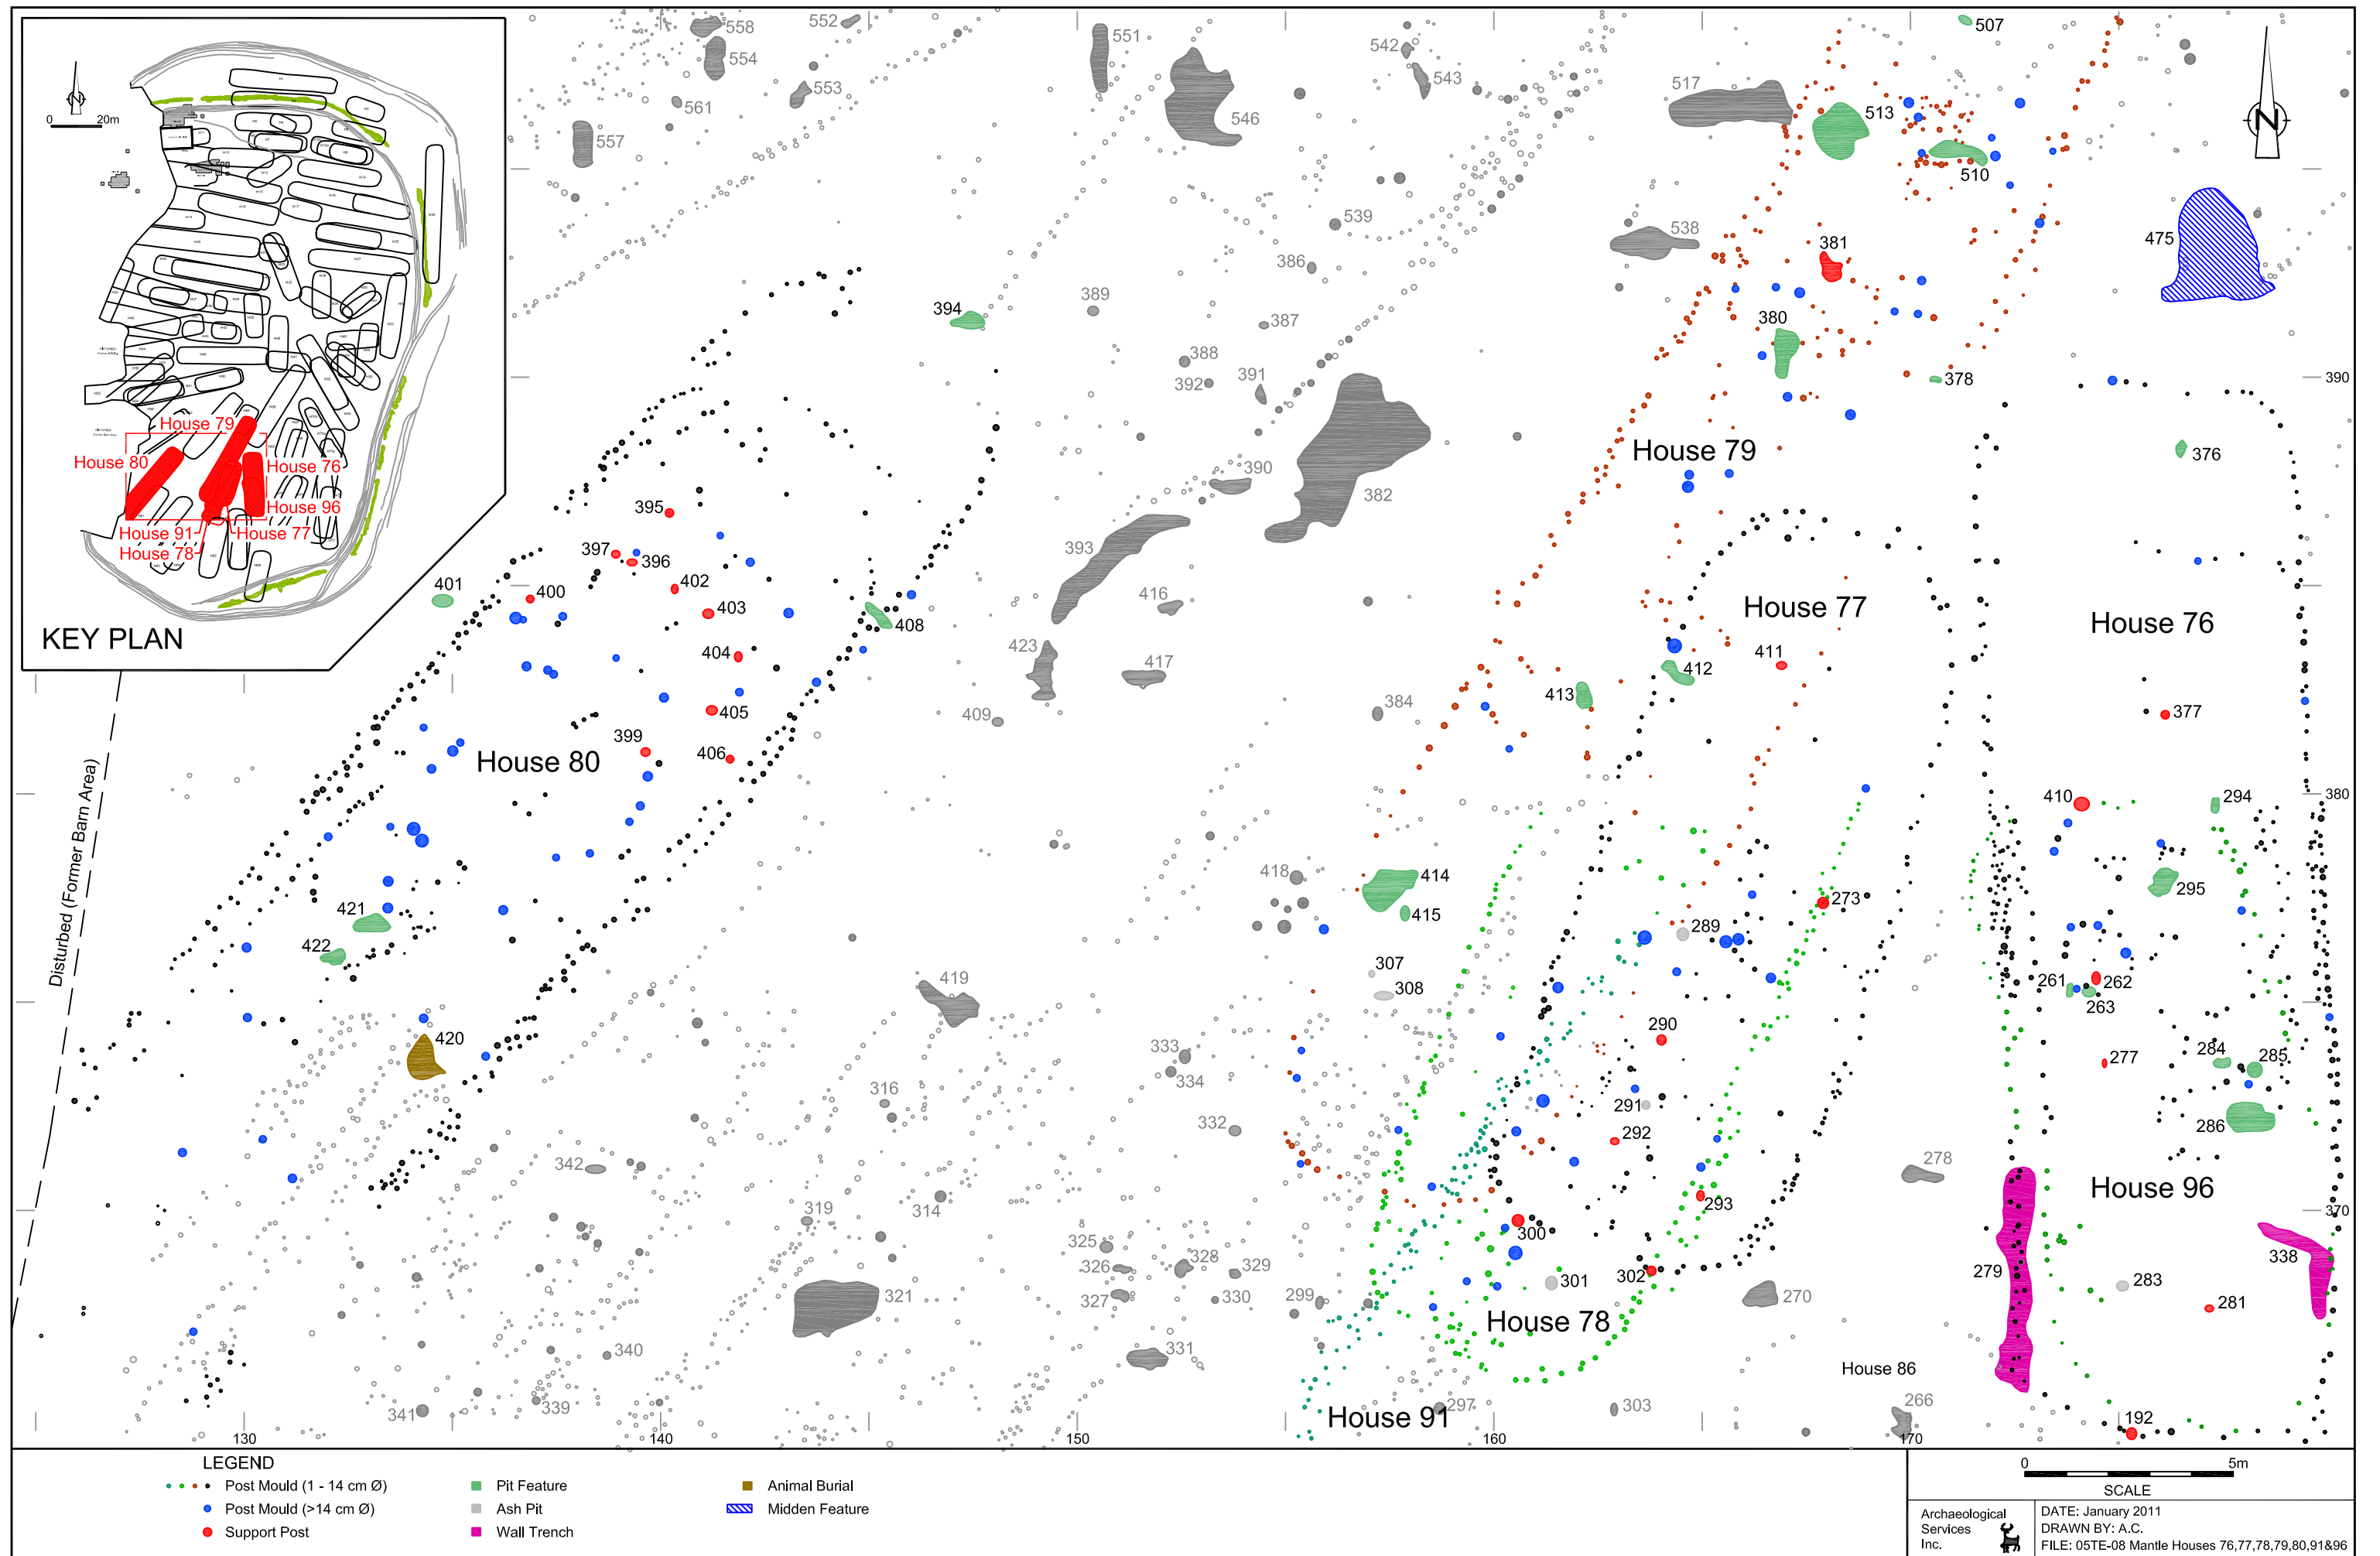

House 76 was a late phase house located in the south area of the site surrounded by Houses 66, 74, 77 and 87 (Figure 5). It was part of a group of four houses, including 77, 85 and 87 that were approximately parallel to each other. It was built over the remains of the earlier House 96 (Figure 7).

This house was 25.4 metres long and 7.7 metres wide, enclosing an area of 188 m<sup>2</sup> and oriented 357° east of north (Table 1). The walls were made up of posts placed in a single row with definite clusters in the central area of both walls. This clustering and wall thickening was the result of either repair or strengthening of the walls in weak areas and resulted in a wall post density of 4.9 posts per metre. These clusters also correspond to the location of the earlier House 96 (Figure 33). The south end of House 76 was semi-circular in shape, while the north end was flatter. The walls at the north end were curved inward with a single row of posts used to close off the end. A 1.8 metre wide opening, likely for a doorway, was found on the west side of the north end. A line of interior posts starting at the south end and running along the west wall probably supported a 0.8 metre wide bunk line. There was another short line of posts in the middle section of the house 0.7 metres from the east wall and measuring 7.5 metres in length that may have been part of an east side bunk line.

Six pit features as well as the densest concentration of large and small posts were located in the area of overlap between House 76 and House 96. As such, these cannot be definitively associated with either structure. However, two wall trenches in the southern end of the house and one pit feature in the northern end of the house can be related to House 76 (Appendix B).

### **House 77**

House 77 was part of a late occupation group of four structures including House 76, 85 and 87, all located in the southern area of the site and sharing approximately the same orientation (Figure 7). It was located 1.2 metres west of House 76 and 6.2 metres north of House 85 (Figure 5). It overlapped early and middle phase houses 78 and 79. This house was 18.5 metres long and 7.4 metres wide, enclosing an area 121 m<sup>2</sup> oriented 19° east of north (Table 1). Average wall post density was 4.1 posts per metre and the walls were comprised of single rows of posts with some areas of post pairs (Figure 33). The ends were semi-circular with similar post arrangements. A 2.1 metre wide doorway opening located in the middle of the south end was the only clear doorway found for this house. Since this house overlaps two other houses it is not clear which interior posts belong to which house. One pit feature, six support posts and two ash pits were contained within this house; however, all were found in areas that overlapped with other houses.

### **House 78**

House 78 was located in the southern area of the site where many overlapping houses were recorded. This house overlapped with Houses 77 and 79 and was most likely occupied during the early to middle transitional occupation phase of the village (Figure 6).

House 78 was missing its north end and was probably disturbed by the later construction and occupation of House 77 (Figure 5). The remaining portion of the house was 15.9 metres long and 7 metres wide oriented 23° east of north (Table 1). If the missing end was located at the northernmost point of the east wall and if it was the same shape as the south end, then the total area of the house would have been 127 m<sup>2</sup>, with a maximum length of 19.5 metres. Offset pairs of posts were used to construct the house walls, which had an average density of 4.9 posts per metre, while the semi-circular south end was made up of a single row of posts. No doorway opening was found in the remaining walls or south end of this house (Figure 33).

There were three ash pits, one pit feature, and five support posts along with eighteen large posts in this house. Of those, only one ash pit, two support posts and four large posts were located in the area of this house that did not overlap with another house (Appendix B).

House 78 was overlapped by the west half of House 77 and the south half of House 79, so the three could not have been contemporary with each other (Figure 33). House 77 was a late phase house, which means that the other two must have been earlier (Figure 6). The north end of House 79 was overlapped by House 65, which was also a late house. Therefore Houses 78 and 79 were occupied at different times during the early to middle transition phase. Given the high concentration of walls from various houses in the vicinity, it was not possible to determine in which order the two houses were built.

### **House 79**

House 79 measured 29.9 metres long and 7.2 metres wide enclosing an estimated area of 232 m<sup>2</sup> (Table 1). The north end of the house was disturbed by the later occupation of House 65, while the limit of the south end was unclear as it was in an area with a very high concentration of wall posts from other houses (Figure 33). The total area and maximum length were estimated by placing the north end adjacent to the northernmost post of the west wall. The maximum length was approximately 36.8 metres.

The density of posts in the house walls was variable. In the centre section of the west wall many posts were placed in offset pairs, while the south end of the same wall had few posts, and these were arranged in a single row. The north section of the east wall was built using pairs of posts, in contrast the south section that had a single row. There was a five metre wide gap in the east wall near the end of House 77

that may have been the result of the disturbance caused by the construction and occupation of that house. The average density of wall posts in the well-preserved west wall was 4.3 posts per metre (Figure 33).

There were eight pit features, two ash pits and two support posts in this house (Appendix B). Most features could not be directly associated with either house. Many of the large posts and support posts were arranged in a linear pattern parallel to the side walls of the house. These posts may have been part of the framework for bunk lines that would have been approximately 1.4 metres wide on the east wall and 1.2 metres on the west (Figure 33).

This house was probably occupied during the early to middle transition phase of the village since both Houses 78 and 79 were overlapped by later phase Houses 65 and 77. Other early houses in the area were Houses 64 and 68 (Figure 6).

### **House 80**

House 80 was located in the southwest area of the village oriented perpendicular to the gentle slope in the southern half of the site (Figure 5). It was occupied in the early phase of the village and was extended once (to the north) (Figure 6). The south end of House 80 could not be located as it was completely disturbed by the construction of the barn.

The remaining portion of the house was 32.6 metres long and 7.3 metres wide. To get an estimate of the maximum length of this house, the south end was assumed to lie within the disturbed area at the top of the break in slope. The estimated maximum length was approximately 39 metres, covering an area of 270 m<sup>2</sup>. The house was oriented 40° east of north (Table 1). The wall posts were placed in pairs, with the densest clustering of posts along the west and east walls. This clustering was probably the result of the reconstruction of the walls when the house was extended. The average wall post density was high at 5.9 posts per metre, which reflects this rebuilding. The original house end was identified by a curved row of posts. There was no clear opening for a doorway identified in the end because of the disturbance caused by house activities and construction from the extension. With this extension the house increased by 4.3 metres in length and it had a semi-circular end (Figure 33). The new end was located in the same spot as the south end of House 64, which was part of the late phase of occupation. Since the two could not have co-existed, House 80 was probably an early phase house (Figure 6).

There were only three pit features, ten support posts, and several large posts in this house. Some of the large posts and support posts form two lines parallel to the walls of the house. These formed bunk lines adjacent to the walls, with the west bunk line being 1.1 metres wide and the east 1.3 metres (Figure 33). Other interior posts would have functioned as additional framing for structural support of the house or as racks associated with cooking areas.

House 80 was part of the early occupation phase of houses along the southern perimeter of the village (Figure 6). Other structures in this group include Houses 82, 84, 85, 86 and 88.

### **House 81**

Much of House 81 was lost as a result of the activities associated with the barn and farming complex. The west wall of this house overlapped with early phase House 80, suggesting that House 81 was a late phase structure (Figure 7).

The walls were constructed using posts placed in offset pairs as well as single rows. Both patterns can be seen in the west wall, and both the west and east walls appear to have been rebuilt during the life of the house. The average wall post density of the well-preserved west wall was 4.4 posts per metre. The south

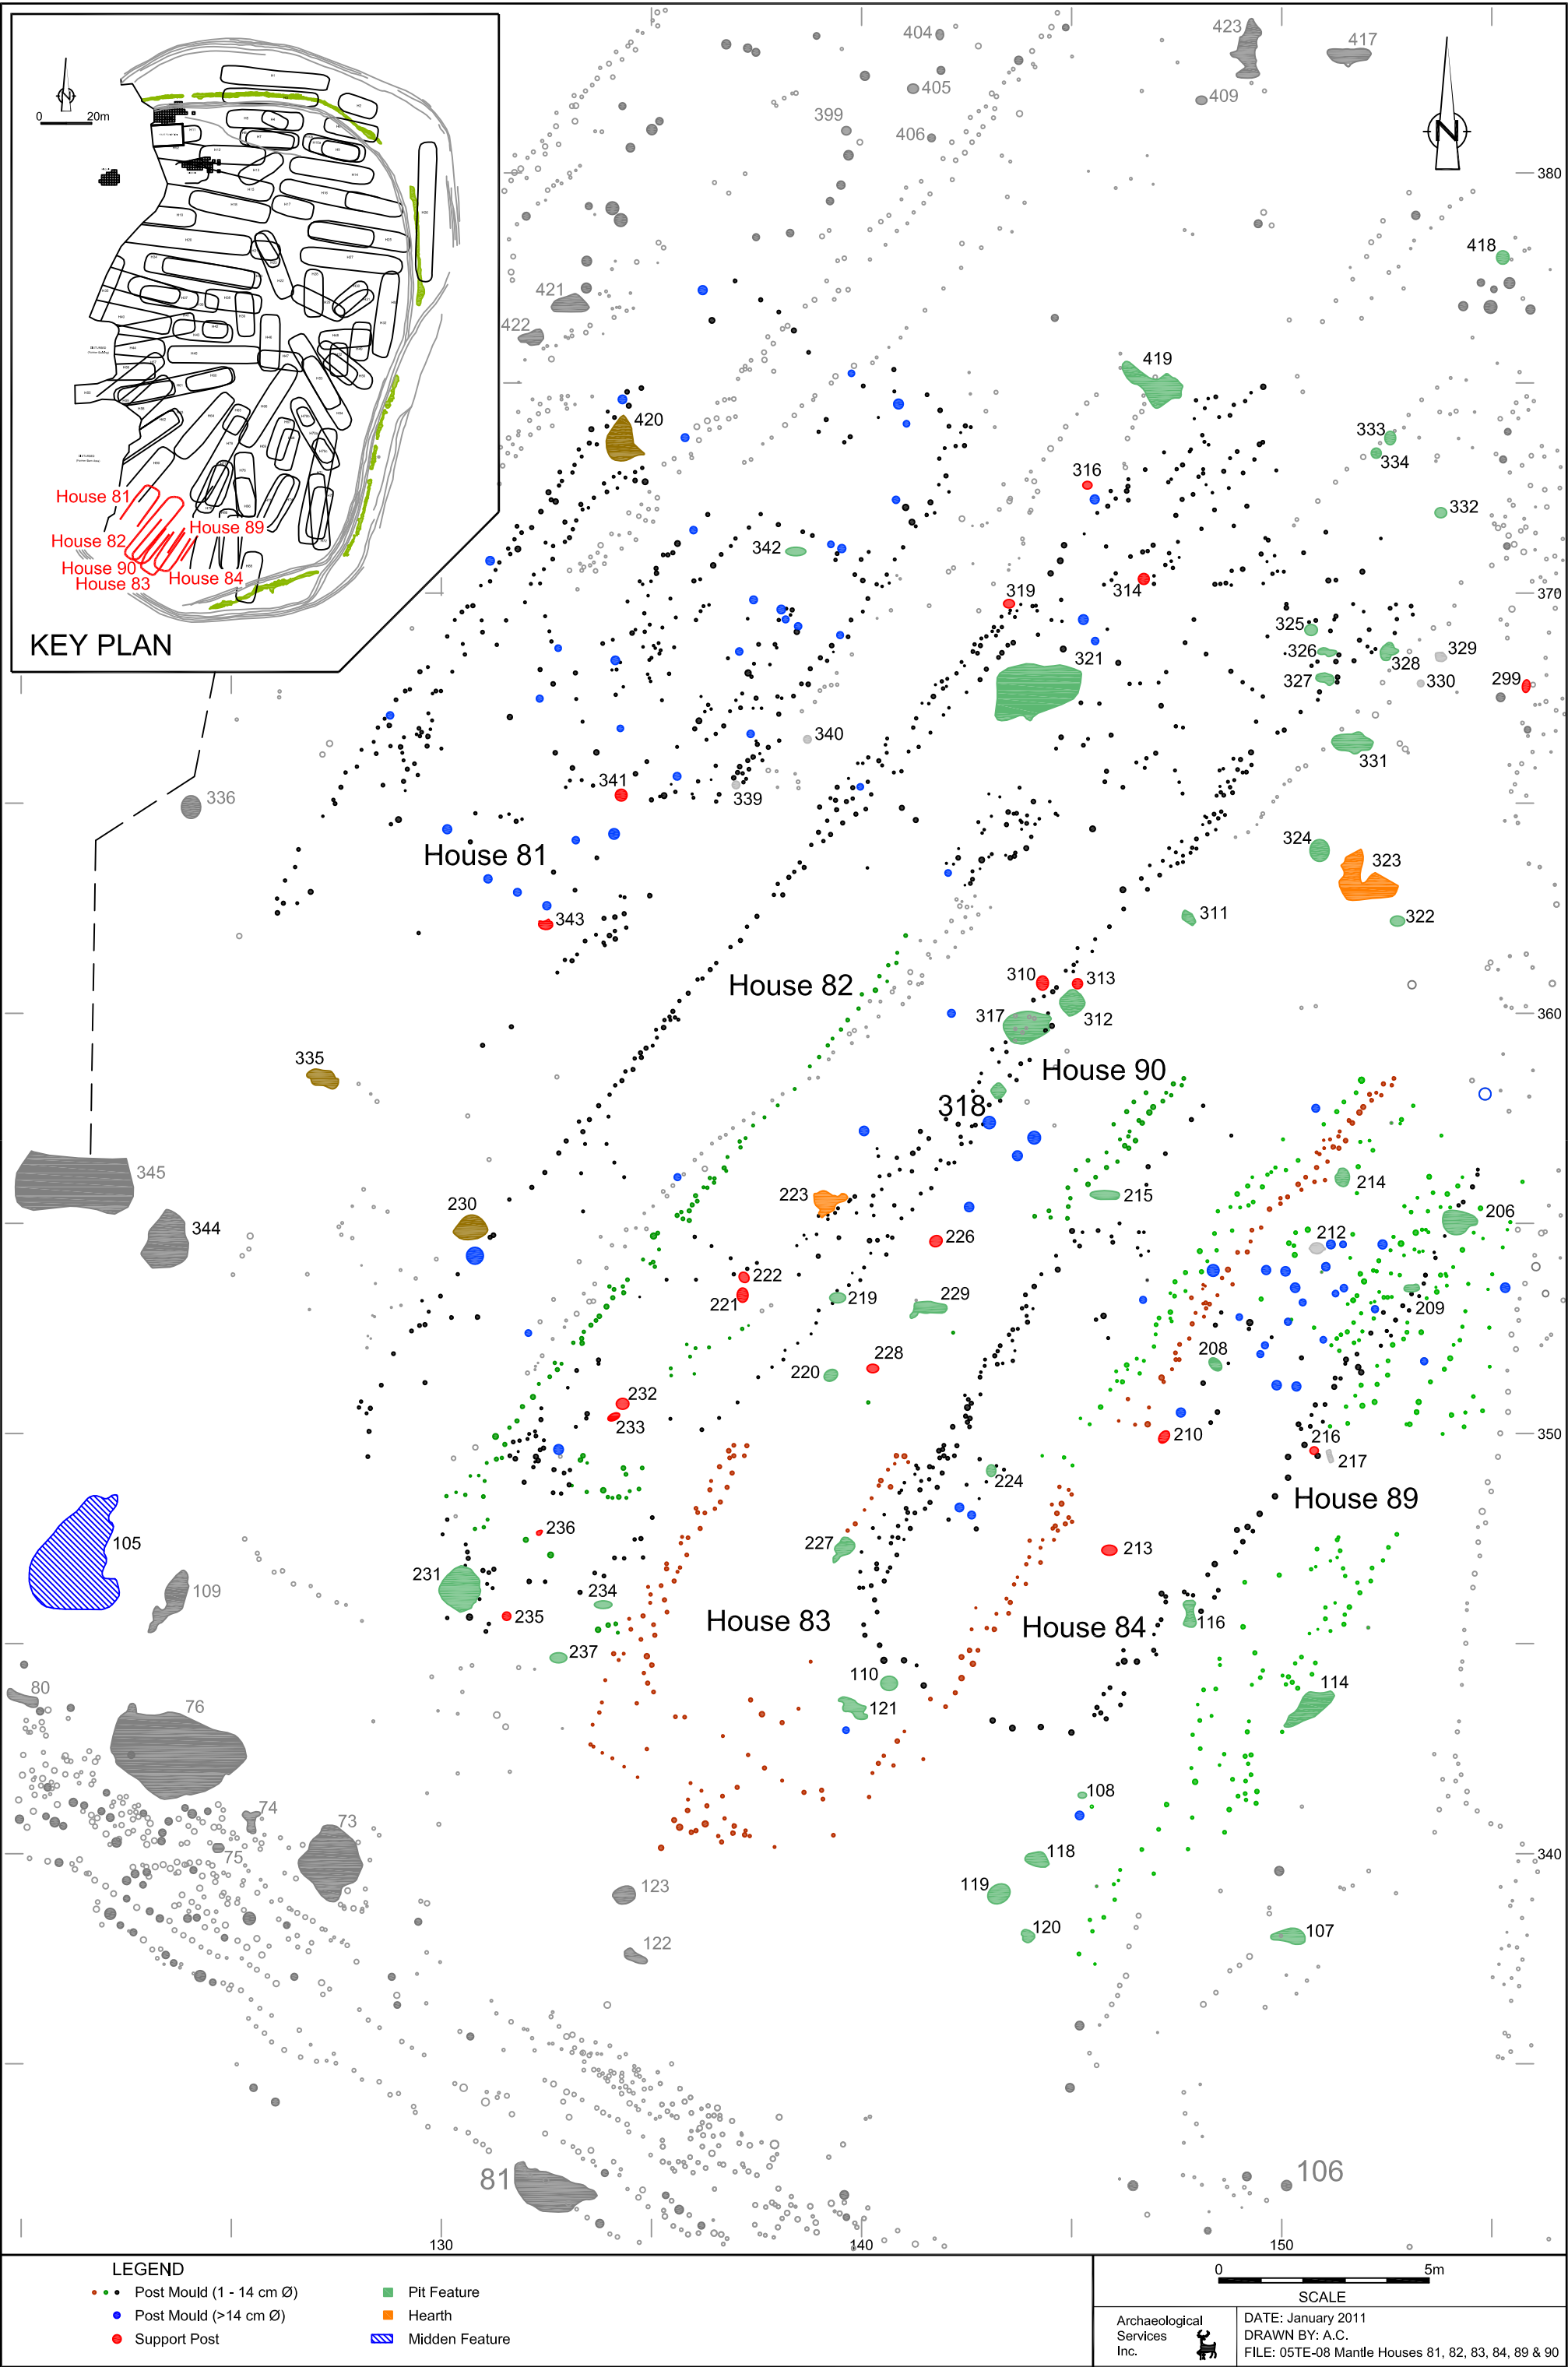

Figure 34: Plan View of House 81, 82, 83, 84, 89 and 90

ends of the walls were tapered slightly, so it was possible to approximate the location of the south end of the house despite the lack of posts perpendicular to the long sides of the house. The north end was clearer as the end of the east wall was tapered and a few posts were found forming a line crossing the long axis of the house (Figure 34). The estimated length of House 81 was 20.7 metres with a width of 7.4 metres, and it enclosed an area of 144 m<sup>2</sup> oriented 36° east of north (Table 1).

One pit feature, one ash pit and two support posts and several other large posts were located in the footprint of this house (Appendix B). A line of large posts 1.2 metres from the east wall would have supported a bunk line along that wall. The east wall of House 80 was located in the area where bunk line support posts would have been for the west wall of this house, so it was not possible to determine if one existed along the west wall (Figure 34).

House 81 was part of the late occupation phase group of houses along the south limit of the village (Figure 7). It may be contemporary with Houses 82 and 84, which share a similar orientation and are sufficiently spaced apart.

### **House 82**

House 82 was a fairly long, early phase house located in the southwest area of the site (Figures 5 and 6). It overlapped with House 90, a late phase house, as well as with a curving row of posts of unknown function (Figure 34). This house was approximately 35 metres long and 7.2 metres wide and would have covered an area of 250 m<sup>2</sup> oriented 40° east of north, parallel to house 80 (Table 1). The location of the north end of the house could only be estimated because it was probably located in an area where there was a high concentration of wall posts from several different houses.

Wall posts were placed in a single row with some clustering, which was probably the result of efforts to strengthen or repair the walls. A single row of posts crossing the long axis of the house was probably the original south end, which was later extended approximately 9.5 metres south to a maximum of 35 metres. The west wall was extended along its original alignment while a new east wall was built for the extension (Figure 34). The average density of posts in this wall was 3.5 per metre.

Six pit features, seven support posts and one hearth were contained within this house (Appendix B). Only four of these pit features and one support post were in a part of the house that did not overlap with House 90, so it is not possible to determine with which house they were associated. Hearths were generally found on or near the central axis of a house, which means that the hearth found close to the east wall of this house was probably contemporary with House 90 instead (Figure 34).

### **House 83**

House 83 was probably a middle transition to late phase house constructed after early phase Houses 82 and 84 were dismantled but before Houses 89 and 90 were constructed (Figures 6 and 7). Portions of this house were found within the footprints of Houses 82, 84, 89 and 90. Part of the east wall, the south end, and a small section of the west wall were found, and the extant portion of the house was 23.2 metres long (east wall) and 7.1 metres wide. This house enclosed a minimum area of approximately 170 m<sup>2</sup> and was oriented 35° east of north (Table 1).

The walls were constructed using posts placed in offset pairs at a density of 4.5 posts per metre. The end was closed off by a single row of posts, and another row of posts crossing over the long axis of the house was found 1.7 metres from the south end. This might have formed an interior wall to create a vestibule that would isolate the doorway from the rest of the house. On the other hand, this may simply have been the house end, and the less substantial row of posts immediately south could have been the framework for

a porch. Two doorway openings were identified in this house: a 1.2 metre wide opening located in the middle of the south end of the house; and another opening in the east wall that measured 1.8 metres wide. A line of large posts parallel to and 1.4 metres from the east wall was likely part of the support framework for a bunk line running along that wall (Figure 34).

If the west wall was extended to the same length as the east wall, then seven pit features and two support posts were contained within the house (Appendix B). Only three pit features were found within a part of the house that did not overlap with any other.

Due to the presence of many overlapping houses in this area, it was not possible to assign these houses to an occupation phase. At least one of these houses would have been occupied during the middle transitional phase. Since Houses 81, 82 and 84 were believed to have been early phase houses, and Houses 89 and 90 were believed to be late, then House 83 was most likely occupied during the middle phase. The degree to which the house walls were truncated and disturbed perhaps suggests that this house was occupied in the early-to-middle phase (Figure 6).

### **House 84**

House 84 was located along the southern limit of the village and may have been contemporary with Houses 81 and 90 (Figure 5), but the poor soil conditions and preservation in this area mean that this statement is speculative. The north end of the house was missing and may have been disturbed by the activities associated with Houses 85 or 89. The north end of the east wall tapered slightly, which could indicate the location of the end of the house (Figure 34). If this was the case, then the estimated house length was 19 metres and the width was 7.1 metres, and the house would have enclosed an area of 127 m<sup>2</sup> oriented 34° east of north, perpendicular to the general slope of the land (Table 1).

There was no clear pattern for the placement of posts comprising the west wall. This wall seems to have been subjected to repair and rebuilding as indicated by the clustering of posts, while the east wall used fewer posts in a linear pattern but not a single row. The average density of wall posts was calculated using the undisturbed sections of both walls, and was estimated at 5.5 posts per metre. The south end was rounded with a 1.8 metre wide opening for a doorway located in the middle. No other doorways were found (Figure 34).

Three pit features, one ash pit and two support posts were contained within this house (Appendix B). None of these features were unique to this house and all were found in areas that overlapped with either House 83 or 89.

### **House 85**

House 85 was part of a group of five houses that included Houses 82, 84, 86 and 88, all of which appear to have been occupied during the early phase of the site (Figure 6). House 85 was located 2.3 metres east of House 87 and 2.1 metres east of House 84 (Figure 5), and measured 23.8 metres long by 7.6 metres wide, enclosing an area of 178 m<sup>2</sup> and oriented 14° east of north (Table 1).

The wall posts were placed in a single row with some posts offset from the row. The north end was open with no row of posts found to close it off, while the south end was semi-circular in shape with a single row of posts used. The average density of wall posts was 2.2 per metre. A unique external entranceway structure was attached to the south end of the house. It was composed of two walls 2.2 metres apart running parallel to the central axis of the house (Figure 35). This structure could have acted as a wind

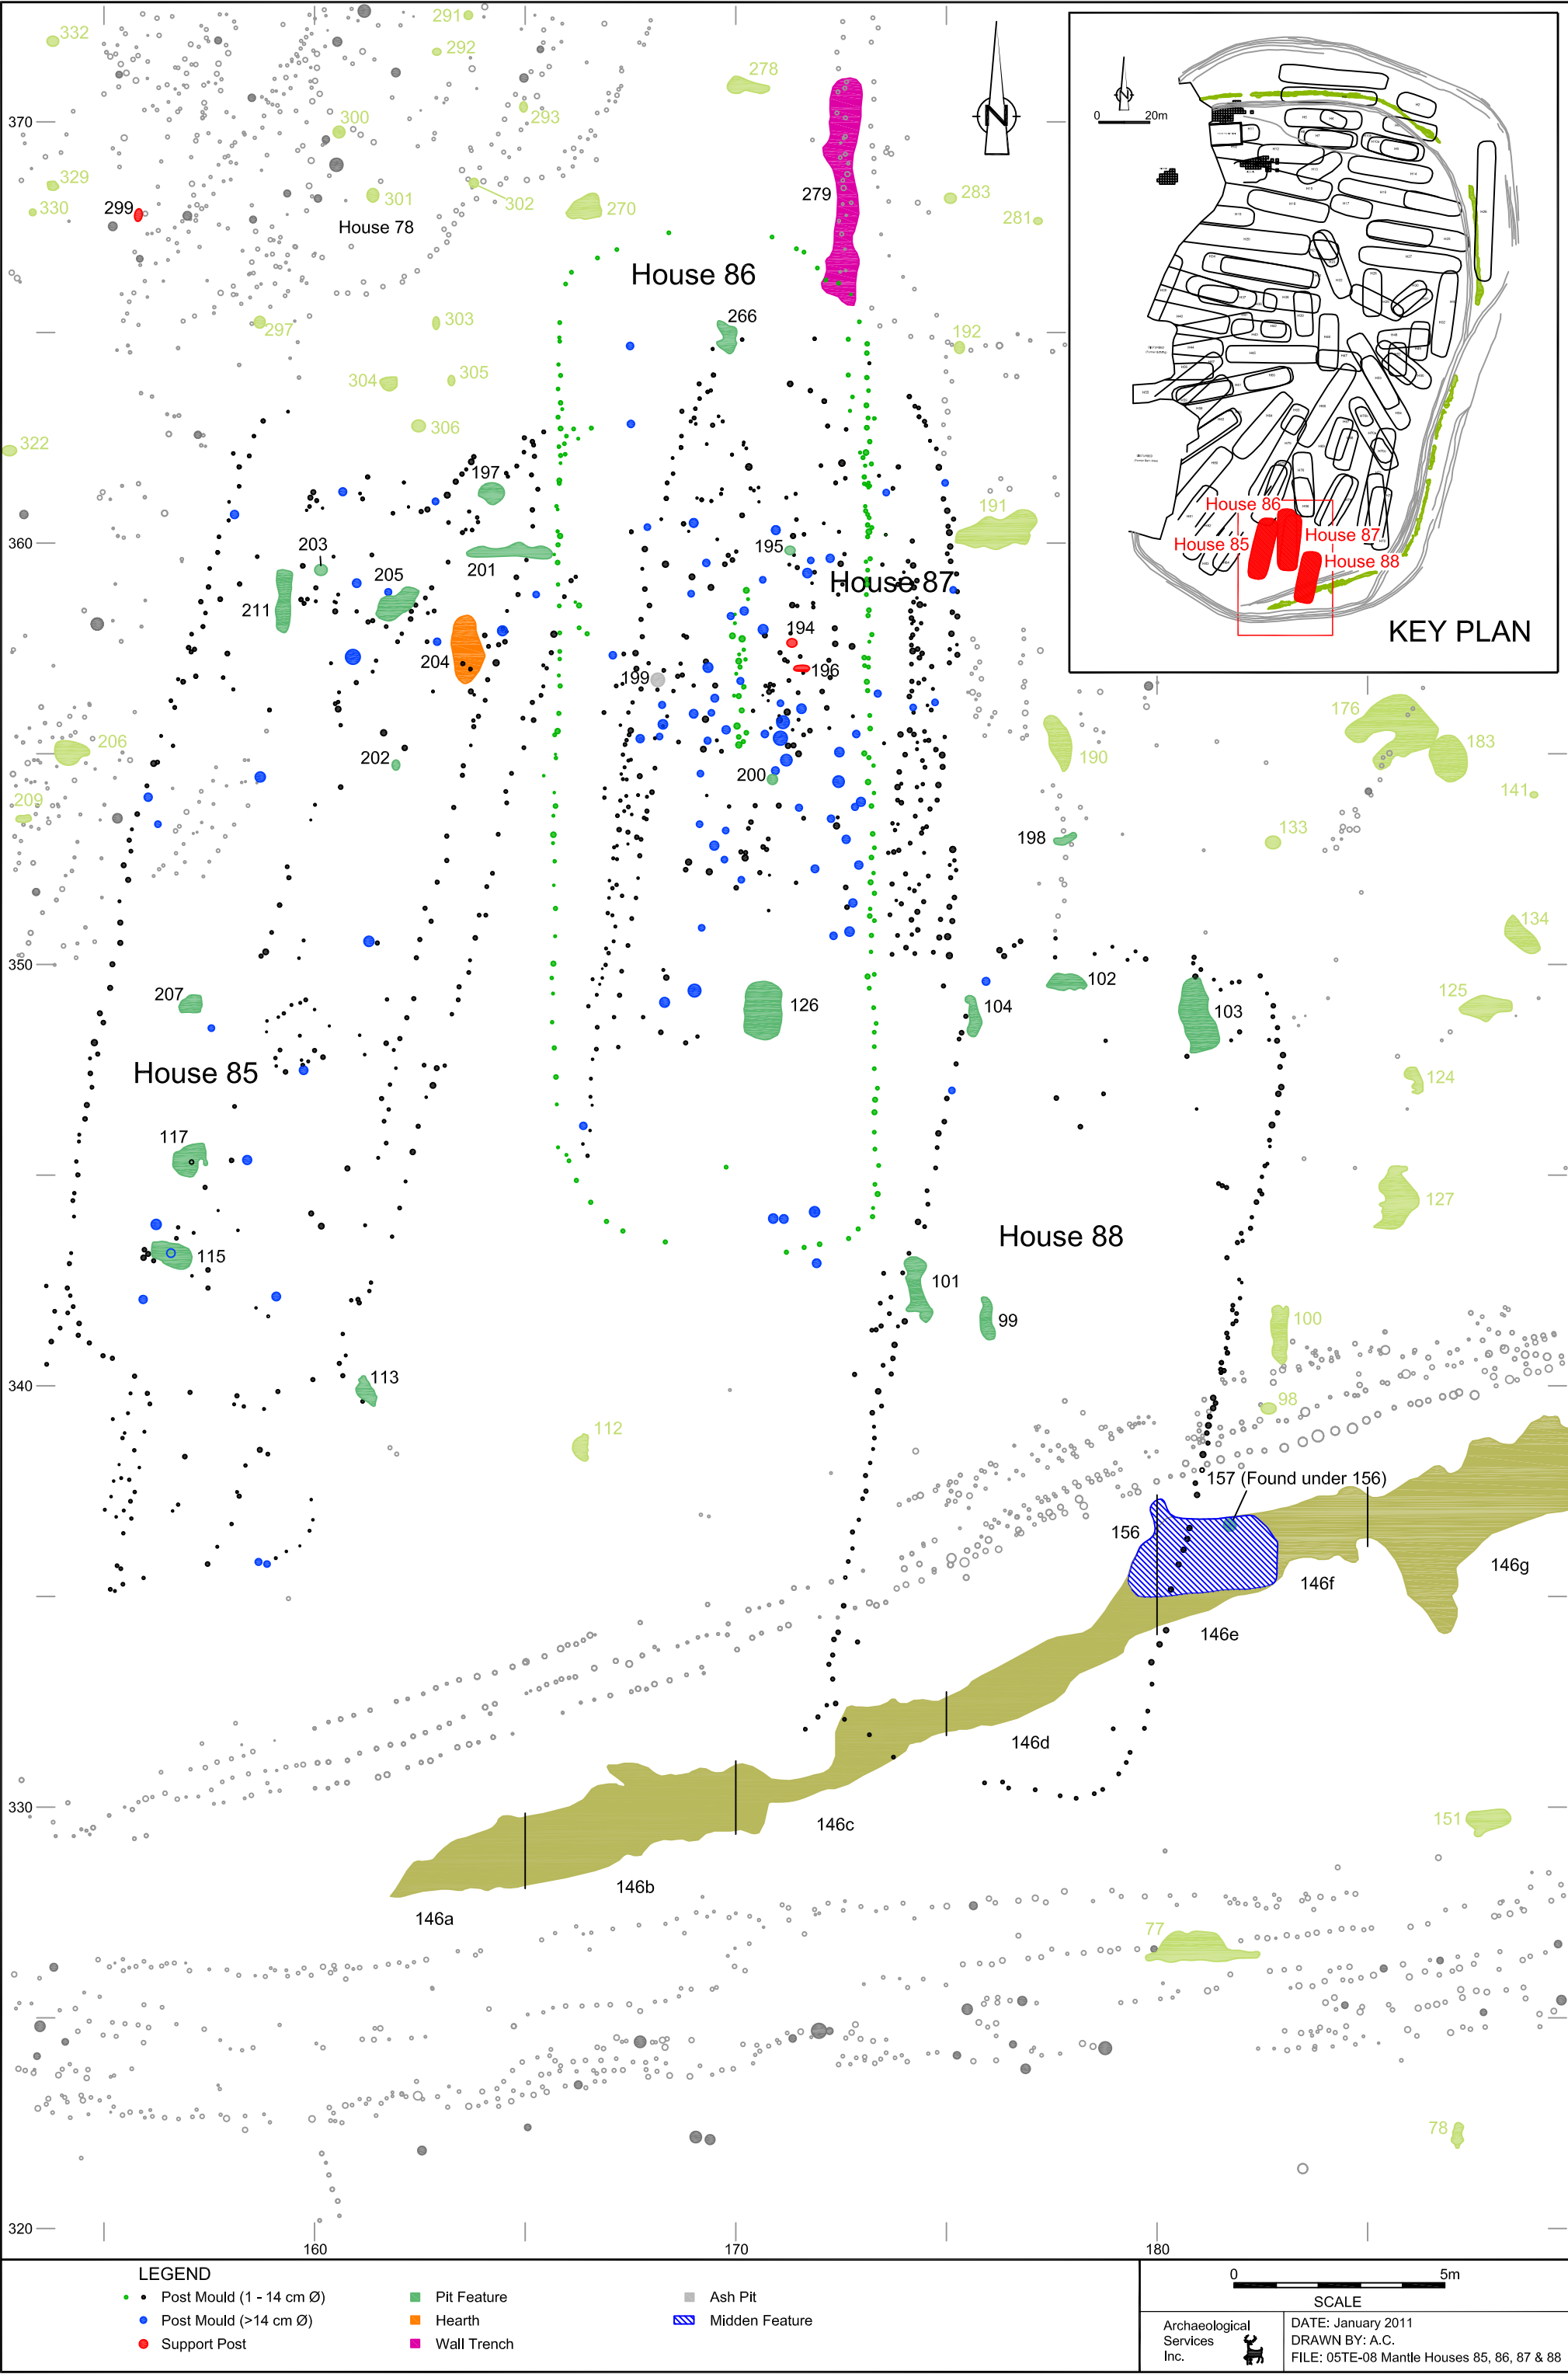

Figure 35: Plan View of Houses 85, 86, 87 and 88

break. The west wall, which would have been the windward side, was made stronger by the presence of more posts while the east wall was weaker with fewer posts used. The east wall of the house may have been rebuilt, as indicated by the presence of two parallel rows of posts, although the westernmost row of the two may simply have been part of a bunk line extending the length of the house.

There were nine pit features, one hearth and eighteen large posts in this house, and this house did not overlap with any other (Appendix B).

House 85 was part of an early phase group of houses located along the south perimeter of the site (Figure 5). The north section of the east wall was located less than a meter from House 86. Given the usual minimum distance of one metre between houses, these two were probably not contemporary with each other. Since House 85 was occupied in the early phase, House 86 was likely part of the late phase of occupation (Figure 7).

### **House 86**

House 86 was located to the south of House 76 and 77, 6.8 metres north of the inner late phase palisade (Figure 5). It was part of the late phase group that included Houses 74, 76 and 77 located in the south area of the site (Figure 35), and was 24.2 metres long and 7.5 metres wide, enclosing an area 174 m<sup>2</sup> oriented 1° east of north (Table 1). The wall posts were placed in a single row, with some clustering in the north half of the east wall and an average wall post density of 2.4 posts per metre. The ends were formed by a single row of posts in a rounded shape. Two openings for doorways were found in this house, one in the north end that was 2.4 metres wide and one in the south end that was 2.8 metres wide (Figure 35).

Much of this house overlaps with House 87, so it is not possible to directly associate features and posts with either house. The four pit features, one ash pit and two support posts contained within this house were in the area common to both houses (Appendix B).

### **House 87**

House 87 was located 2.5 metres east of House 85, 1.1 metres west of House 88, and was oriented at approximately the same angle as the other two (Figure 5). The south end of this house was missing and was likely disturbed by the later construction and occupation of House 86. Assuming a minimum distance between houses of one metre, it was possible to approximate the location of the south end. If the south end was located in roughly the same location as the south end of House 87, then this house was 21.5 metres long, 7.4 metres wide, and enclosed an area of 145 m<sup>2</sup> (Table 1). It was oriented 8° east of north (similar to Houses 85 and 88).

The walls were generally constructed with posts placed in a single row, but there were some sections where posts were paired or offset from the alignment of the wall. There were some additional post rows in the central section of the east wall, which were probably the result of rebuilding episodes. The north ends of the walls were relatively well preserved and were tapered, and the house had a wall post density of 5.5 per metre. The final shape of the south end was not clear because of the disturbance from overlapping House 86 (Figure 35).

Much of the area of this house overlaps with House 86, and therefore posts and features found in the area common to both houses cannot be directly associated with either house. Nevertheless, it should be noted that the feature and post density contained within the footprint of this House is much greater than that of House 86, which may suggest a more intensive occupation of House 87. Four pit features, one ash pit and two support posts as well as many interior posts were contained in the footprint of these two houses (Appendix B). A line of posts found inside House 87 one metre from the east wall was probably part of a

bunk line. A second line of larger interior posts parallel to the west wall could have been supports for another bunk line that was 1.6 metres wide (Figure 35). The rest of the interior posts were probably used for the internal framing of either house and/or for cooking activities that took place in the central area of each house.

House 87 was part of a group of houses associated with the early phase of the village's occupation in the southern most area of the site (Figure 6). This group included Houses 82, 84, 85 and 88, which were all contemporary with the original outer palisade that first surrounded the village.

### **House 88**

House 88 was the southernmost house in the village (Figure 5). It was located 2.2 metres north of the early palisade and was overlapped by the late phase palisade and the associated linear trench. The trench (Feature 146) was located outside of and parallel to the late phase palisade, and was used as a midden during the late occupation of the site (Figure 7). Posts from the wall of this house were found in the subsoil below the fill of the trench, indicating that House 88 pre-dates the inner palisade and the associated trench feature and can definitely be associated with the early phase of the village's occupation (Figure 6).

This house was 20.3 metres long and 7.8 metres wide, enclosing an area of 147 m<sup>2</sup> and oriented 12° east of north (Table 1). Sections of the walls were built using offset pairs of posts while others had posts placed in a single row. The average wall post density was 2.7 posts per metre. The ends of the walls were curved inward with a single row of posts used to close off each end. A 2.1 metre wide opening for a doorway was found in the south end of the house. There were no interior posts to indicate the presence of a bunk line or large support posts for the internal support structure of the house (Figure 35).

Five pit features were contained within this house (Appendix B). Several external pit features were located east of the house in an area of the site that was maintained as an open activity area throughout the occupation of the village.

House 88 was part of a group of houses that was occupied during the early phase of the village (Figure 6). Other houses in this group included Houses 82, 84, 85 and 87.

### **House 89**

House 89 was likely a late phase house that post-dated Houses 83 and 84 and was contemporary with Houses 86 and 90 (Figure 7). It was defined by partial wall sections and some larger posts that were probably part of the interior framing of the house (Figure 34). The ends of this house were missing, but, if the four features identified in the area south of the remaining house walls (Features 108, 118, 119 and 120) were contained within the house, then the south end would have been five metres from the palisade. The presumed location of the north end was based on the assumed one meter buffer between houses. The estimated length of this house was 29 metres with a width of 7.3 metres. This house covered an area of 188 m<sup>2</sup> and was oriented 36° east of north, similar to House 90 (40° east of north), which was located three metres to the west (Table 1).

The extant wall sections were composed of posts that were either placed in a single row (as in the east wall) or clustered in pairs (as in the west wall). This house overlaps with parts of Houses 83 and 84, so the features and interior posts contained within the area common to all three houses cannot be directly associated with one particular house (Appendix B).

## House 90

The condition of House 90 was very similar that of to House 89 (see above). Only portions of the walls were extant and both ends were missing. To get an estimated length for this house, the south end was assumed to have been approximately five metres from the palisade and the north end was assumed to be one metre from other late phase houses. The estimated maximum length of the house was 30 metres with a width of 7.0 metres and a total enclosed area of 195 m<sup>2</sup> oriented 40° east of north (Table 1). The walls of the house were constructed using posts placed in offset pairs with some sections having only a single row of posts. There was a row of large posts and support post parallel to the east wall that could have been part of the frame for a 1.3 metre wide bunk line (Figure 34).

Eleven pit features, one hearth and ten support posts were contained within the footprint of this house (Appendix B). The hearth was probably associated with this house because it was located on the central axis of the house. Eight of the pit features were found in a portion of the house that did not overlap with any other, so they were likely associated with this house.

House 90 was occupied during the late phase of the village (Figure 7). It is not known what caused the disturbances to this house and those adjacent to it, but these might have been the result of farming activities since other houses in this area dating to different phases of the village were also impacted (Figure 5).

## House 91

House 91 was represented by a partial house end and a single line of wall posts oriented 36° east of north and overlapping the south ends of Houses 77 and 78 (Figure 5 and Table 1). This area of the site is very dense with several overlapping houses from different phases, so it was not possible to determine if this wall was the east or west wall of the house (Figure 33). Since House 77 was a late phase house and House 78 was part of the early to middle transition phase, the extant portion of House 91 may have been part of an original, early house constructed during the earliest occupation of the site. It is difficult to associate House 91 with either phase of occupation because it was so heavily impacted by the construction of and activities in the later houses, leaving evidence of a single wall. This disturbance further supports the suggestion that the house was occupied at a very early point in the village's occupational history, since so little of the house was preserved.

## House 92

House 92 was located in the northwest area of the site and was directly impacted by the construction of the farmhouse (Figure 5). It was an early phase house overlapping with later Houses 11 and 12, and was part of the established group of houses located on the top of bank overlooking Stouffville Creek. Midden 1 was located close to west end of House 92, and this house was contemporary with Houses 15, 18, 19 and 20 (Figure 6). The east end of the house was disturbed by the construction of House 12, so it was not possible to estimate the location of the east end. The west end would have been located near the top of slope, and the estimated house length was 32 metres and with a width of 6.0 metres. The minimum area enclosed by the house would have been 237 m<sup>2</sup> oriented 97° east of north (Table 1).

The walls were constructed by placing posts in a single row with additional posts included for extra support (Figure 12). The average wall post density was 5.4 posts per metre, which suggests a lengthy occupation. The section of the house that was exposed contained two pit features, eight support posts and two hearths (Appendix B). There were no overlapping houses in this section so all of these features, hearths and posts were associated with this house.

### **House 93**

House 93 was located on the east side of the site and was oriented 5° east of north (Figure 5 and Table 1). The close proximity of House 93 to the inner late palisade, along with the fact that this house overlaps with the northeast portion of House 32 (which has been assigned to the late phase of occupation), means that House 93 was probably constructed during the early phase of the village's occupation (Figure 6).

House 93 was a small house measuring 16 metres long and 7.7 metres wide, enclosing an area of 115 m<sup>2</sup> (Table 1). The house walls were incomplete due to disturbance, but the extant sections had a density of 2.7 posts per metre and were composed of single rows of posts with some clustering in the north end of the west wall. Not much remained of the south end, but the north end was squared off with a single row of posts used to close off the end (Figure 19).

Six pit features were contained within the footprint of this house (Appendix B). There were several pit features of unknown association in the area of this house, so the ones found within the house might be part of the late phase of occupation and not actually associated with House 93.

House 93 was too close to the inner palisade for them to have been contemporary with each other (Figure 5). This house was likely built around the same time as House 26, which was located 4.5 metres to the east and was also part of the early occupation of the village. The relative paucity of posts and features in the house may indicate that this was a semi-permanent or temporary structure.

### **House 94**

This house was originally identified as a smaller house located within the footprint of House 37 (early phase). Upon closer examination of the construction sequence of House 37, the end that was thought to be the east end of 94 was in fact an original east end of House 37 (Figure 20). Therefore, House 94 should not be considered to have been an actual structure.

### **House 95**

House 95 was a small structure located 2.3 metres north of House 11, with the same alignment as the north inner late phase palisade (Figure 5). Since this house and the palisade could not have co-existed, House 95 would have been occupied in the early phase prior to the palisade's construction (Figure 6). It was probably contemporary with Houses 1, 3, 5, 7, 12, 15 and 92.

This house was heavily impacted by the foundation of the farmhouse that occupied the site until shortly before excavation commenced (Figure 12). The length of the extant portion of House was 8.5 metres, with a width of 5.9 metres. The estimated length, based on the distance to the slope and the proximity of contemporary House 92, is 22.0 metres. At this length, the house would have enclosed an area of 130.9 metres (Table 1).

The walls were built using posts placed in a single row that tapered at the east end to form a semi-circular end (Figure 12). Unfortunately, there were not enough undisturbed segments of the house wall that could be used to calculate wall post density. The west end had been completely disturbed by the construction of the farmhouse and the septic bed. There were no features found in this house.

### **House 96**

House 96 was a house that was mostly obscured by the footprint of late phase House 76 (Figure 33). It has been placed in the early phase of the village's occupation (Figure 6).

House 96 was 16.4 metres in length and 6.9 metres in width, enclosing an area of 103.2 metres and oriented 350 degrees east of north (Table 1). Since this house was located almost entirely within the footprint of the later House 76, no features or support posts could be definitively assigned to this house. However, most of the features and large posts found within the footprints of Houses 96 and 76 cluster in the north end of House 96, suggesting that they may belong to this house (Figure 33). Where they were preserved, posts were aligned in single and paired rows with an average wall post density of 4.4 posts per metre.

## **2.4 Palisades**

Cross-culturally, defensive fortifications are the most costly and largest examples of pre-industrial military technology (Keeley 1996:55). The investment in constructing, rebuilding and maintaining these palisades suggests that defense was an important concern for the inhabitants of the Mantle village.

The occupation of the Mantle village involved three separate phases of palisade construction. Since the later phases of the palisade are superimposed upon earlier structures, this village contracted over time rather than expanded, though there is significant overlap between all palisade phases (Figure 5). Although the western edge of the site is disturbed and unexcavated in some spots, it would appear that the western side of the palisade remained fixed at the top of the slope leading to Stouffville Creek throughout the occupation of the village.

The number of rows in the palisade varies from one to nine, depending on the section of palisade in question (see below). Instances in which more than three rows of palisade posts were excavated in a single location are interpreted as evidence of rebuilding that is consistent with multiple phases of palisade construction. There are no ethnographic descriptions of palisades of this thickness, and Engelbrecht (2009) argues that more than three rows were unnecessary. Those sections with only three rows (e.g., parts of the second and third palisade phase in the southeast corner) more accurately reflect the three rows that would have been standing at any given time.

### **2.4.1 Palisade Phasing**

Determining the order of palisade construction was essential to understanding the occupational history of the Mantle village. Superimposition of houses, features (particularly the trench midden surrounding the late phase palisade), relative wall post densities and relative densities of palisade posts were used to determine the construction order for each palisade phase. In this way, the methods used are similar to, and inseparable from, those used to sort houses into early and late phases of village occupation.

#### ***Palisade Phases 1 and 2: Early***

Palisade Phases 1 and 2 were evaluated together because many sections of these two palisades overlapped (Figure 36). Based on the relative densities of palisade posts and house placement relative to the Phase 1 palisade, it would appear that Palisade Phase 1 was replaced by Phase 2 relatively soon after its initial construction. These two phases of palisade construction were contemporary with the early phase of the village's occupation.

Figure 36: Palisade Phases 1 and 2

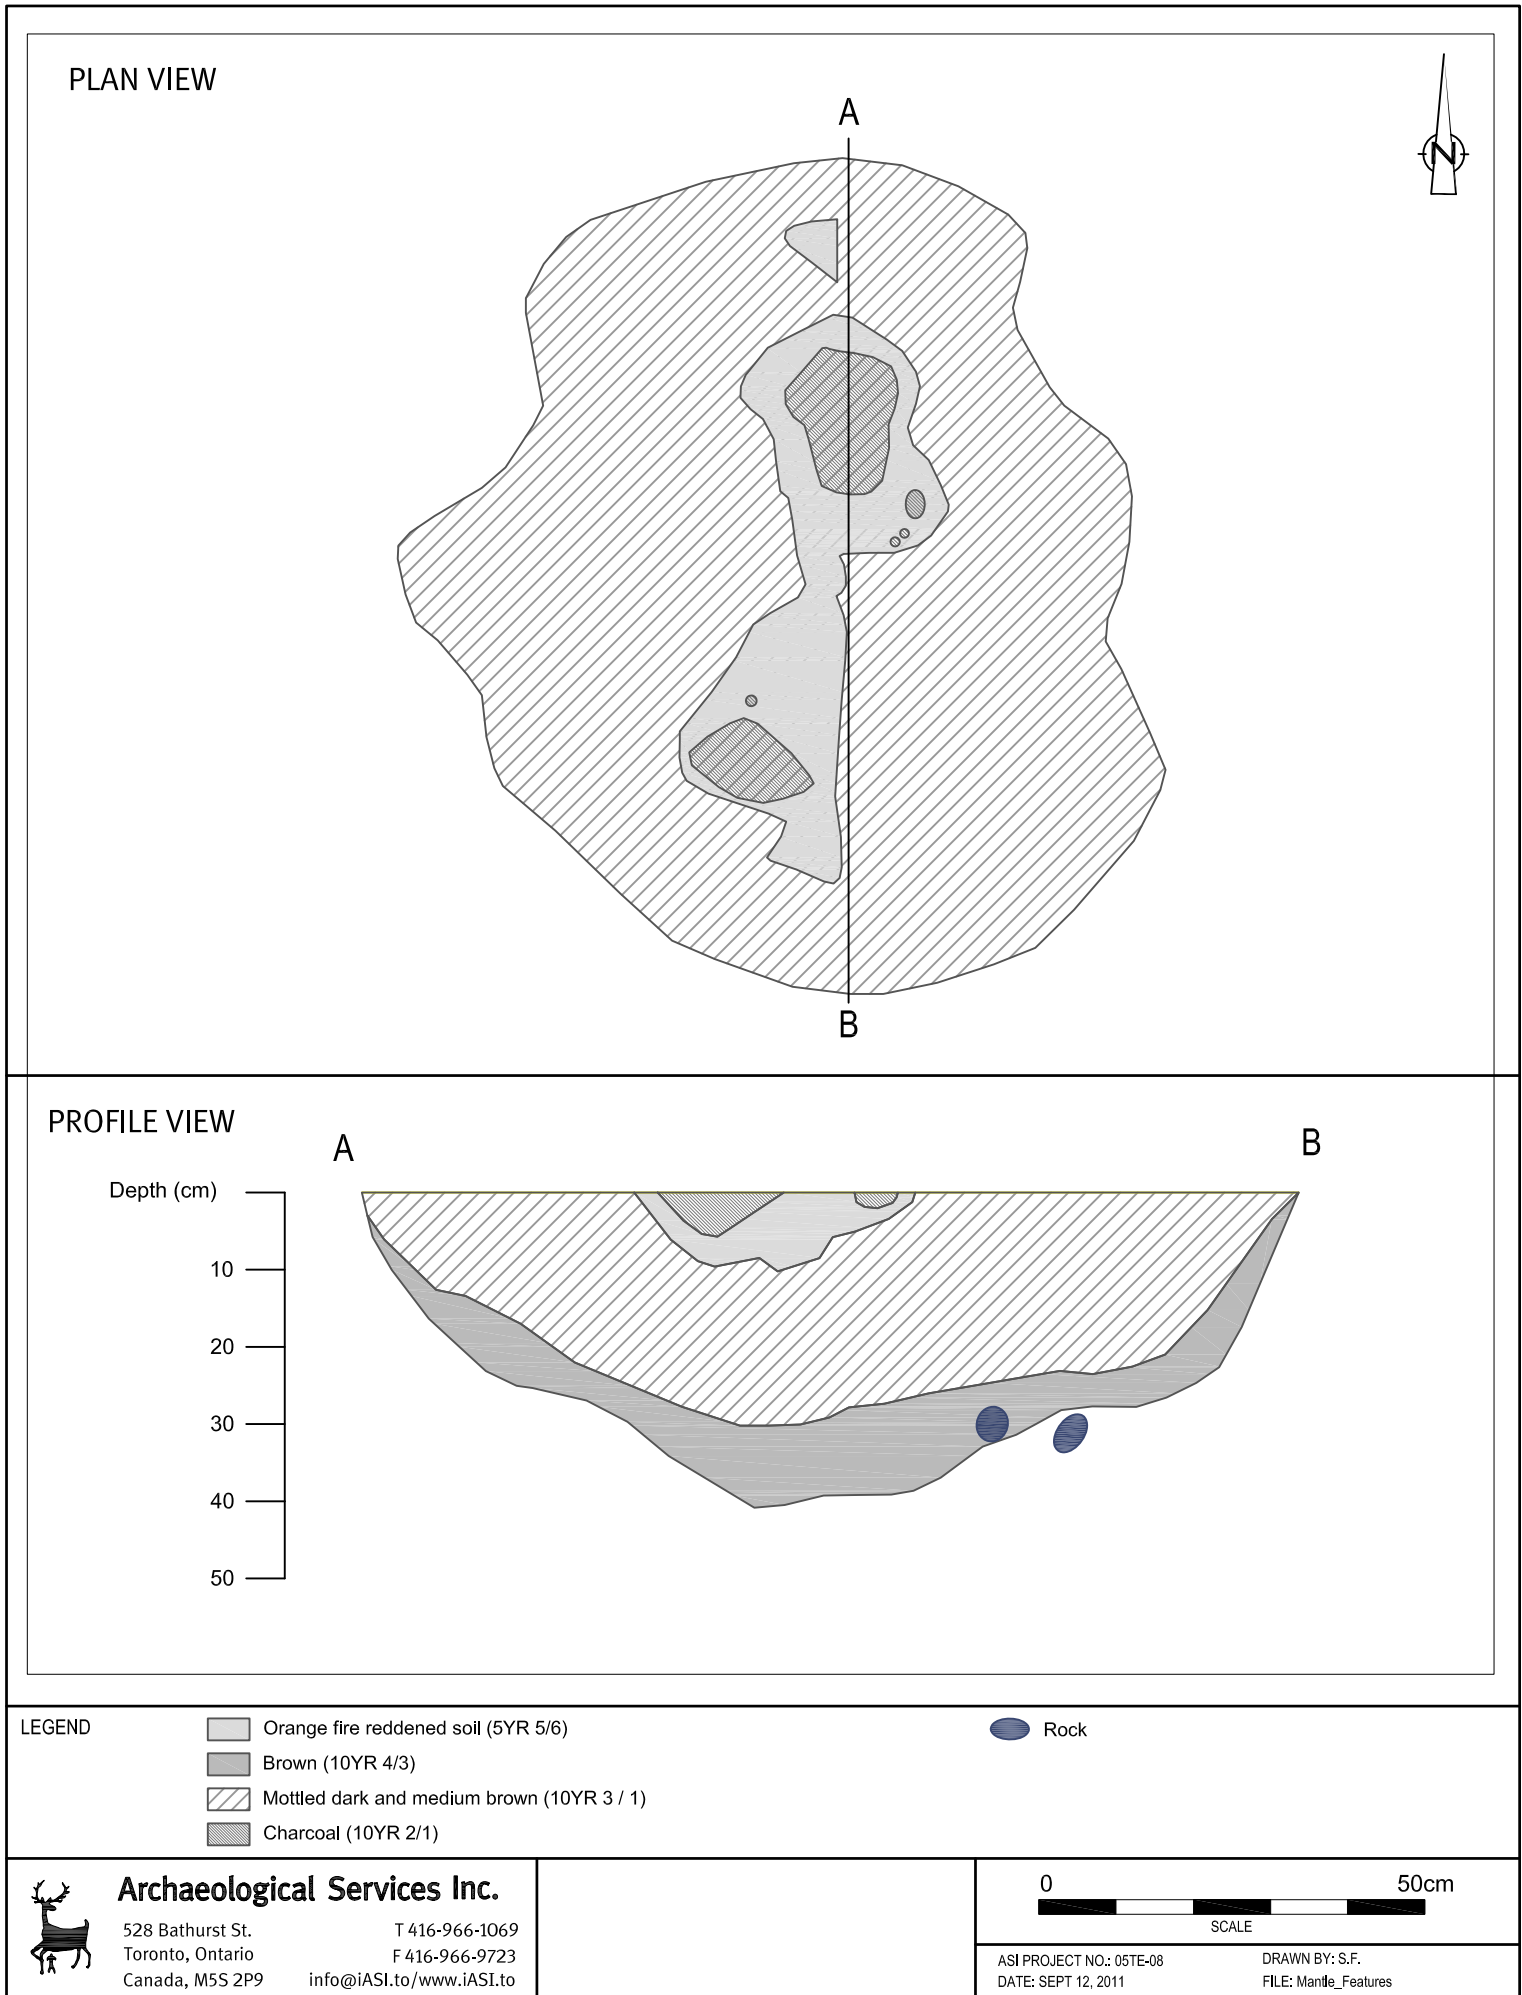

Palisade Phase 1 was the first constructed, and was represented by the outermost rows of posts around the village (Figure 36). This palisade enclosed an area of approximately 2.8 ha. On the northern side of the village this palisade was represented by five rows of posts, arranged in single parallel lines. These likely represented a double and triple palisade, belonging to each of the first and second palisade phases. At the very top of the village, immediately left of the central axis of the site, there was a dense cluster of posts on top of a hearth feature (Feature 59) that post-dates the palisade (Figure 37). These posts may have been the result of the rebuilding or strengthening of the palisade, or they may have been related to activities that took place around that hearth.

After this dense cluster of posts and continuing east (clockwise) around the palisade, the pattern returned to five rows of posts with some gaps probably owing to poor soil conditions. This continued until approximately one-third of the way down the east side of the village, where there was a split between the first and second palisade phases. Immediately before this split was an opening in the palisade with a few posts closing the opening, which may have been an entrance into the village. In the first phase of palisade construction, this entrance was 28 metres in width; in the Phase 2 palisade, this opening narrowed to 12 metres. There was one hearth feature (Feature 41) immediately in the centre of this 28 metre wide gap in the Phase 1 palisade (Figure 38). As noted above, this feature may have been an outdoor cooking hearth utilized during the occupation of House 26. Its association with this entrance to the village was also significant.

Continuing clockwise (south), along the outer Phase 1 palisade, the previous two to three row palisade narrowed to one row of single and paired posts for a distance of approximately 40 metres. This then expanded into a section where there were four rows of single and paired posts for 25 metres, followed by two rows of posts with a three metre gap between them for a distance of 15 metres. The next 18 metres of palisade had a scattering of posts with one clear row of posts running through the central area. The soils in this area of the site were relatively poor and unstable, which may explain the narrowing and seemingly erratic construction of the palisade in this section. In the southeast corner of the village, a more regular pattern of post placement in the Phase 1 palisade resumed around the southern limit of the village, where the Phase 1 and Phase 2 palisades merged again. This section of palisade was composed of six distinct rows of posts, suggesting that both palisades were composed of three rows of posts in each phase.

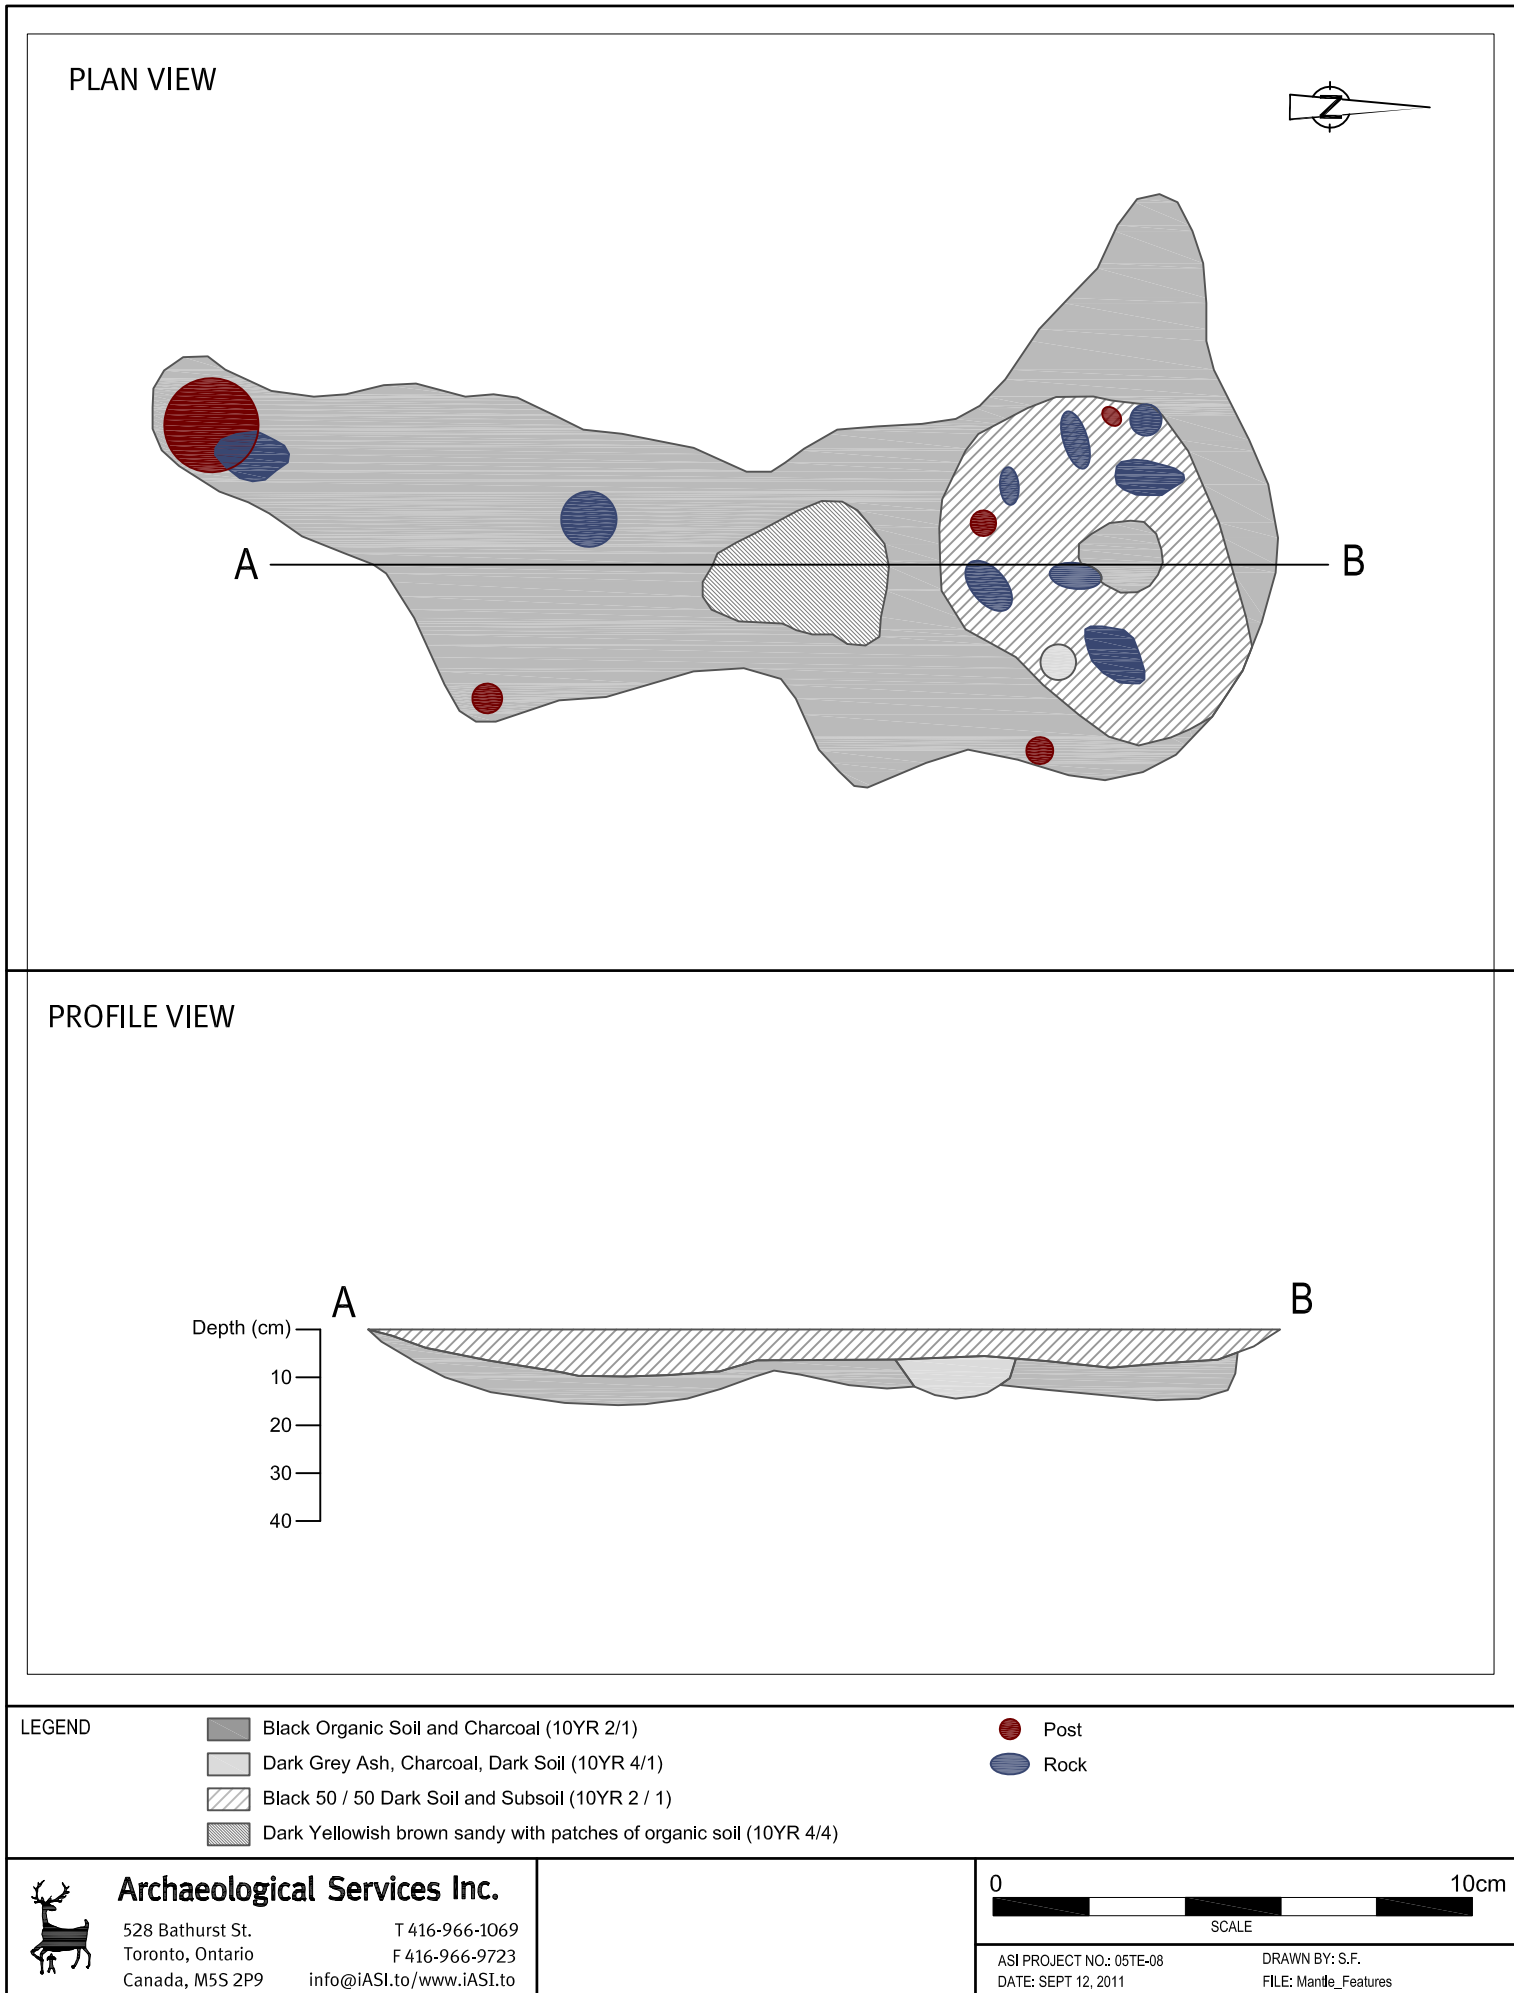

Figure 38: Plan and Profile View of Feature 41

As noted above, the Phase 2 palisade diverged from the Phase 1 palisade approximately one-third of the way down the eastern side of the village. The Phase 2 palisade dipped in slightly to the west and was composed of two or three rows of posts for a length of 30 metres. It then merged with the later Phase 3 palisade. This section of palisade where the Phase 2 and 3 palisades overlapped extended for 90 metres along the east side of the village and was composed of a minimum of three and a maximum of seven rows. There were two gaps, two and three metres long, respectively, mid-way along this section that may have served as entrances to the village (though they may also be the result of poor preservation and/or the loss of a section of posts during excavation). While it was not possible to assign individual rows of palisade posts to one or another phase, as noted above it is unlikely that the palisade was composed of more than three rows of posts at any given time.

In the southeast corner of the site, the three palisade phases diverge. The Phase 2 palisade was located in the middle of the three and was composed of three lines of parallel and paired posts with additional posts that probably indicate some rebuilding and/or strengthening. Hearth features 83 and 89 and pit feature 91 overlapped with this section of palisade and were either related to activities within the village precinct in the first palisade phase (early village) or activities outside the village in the third palisade phase (late village) (Appendix B).

Since the density of palisade posts in the first palisade phase on the eastern side of the site was very low, this section of the first phase of palisade construction may have been very short-lived. Very early in the life of the village, a decision seems to have been made to reconstruct that portion of the palisade eight to ten metres further west, perhaps because soil conditions were better, resulting in a reduction of approximately 1060 m<sup>2</sup> in the total enclosed area of the village.

This initial contraction of the palisade did not affect any of the structures in the village (as was the case with the later Phase 3 contraction), so Phases 1 and 2 were lumped together in order to simplify the reconstruction of the occupational history of the site. The fact that no houses were constructed adjacent to the Phase 1 palisade in the southern portion of the site lends further support to the idea that this contraction occurred very early in the occupation of the village.

### ***Palisade Phase 3: Late***

The third and final phase of palisade construction corresponded to the late phase of the occupational history of the Mantle village. This final contraction of the palisade reduced the northern portion of the village by a further 3170 m<sup>2</sup> and the southern portion of the village by 460 m<sup>2</sup>. This new configuration of the palisade necessitated the dismantling of Houses 1, 2, 3, 6, 93 and 88 and the contraction of Houses 16 and 25 (Figure 5). It is unknown whether or not these houses were abandoned prior to or because of the contraction.

In this phase the construction of the palisade appears to have been more uniform than in the previous phases. Three rows of palisade posts placed in single rows were evident across the northern portion of the site, with the exception of the northeast corner where there were a few areas where it appeared that the palisade was constructed using only two rows of posts. Alternatively, this may also have been the result of poor preservation as some posts in this area may have been related to a third row. The eastern side of this palisade appeared to have been relatively well-constructed, with three distinct rows of posts observed to the point where this palisade phase merged with the remains of the Phase 2 palisade. Up to seven rows of posts were apparent where these phases overlapped, suggesting that the Phase 2 palisade was completely dismantled and that the Phase 3 palisade was constructed to replace it.

In the southeast corner of the village the third phase palisade was contracted slightly, effectively cutting off that corner of the village and reducing the palisaded enclosure by 460 m<sup>2</sup> (Figure 36). This portion of

the third palisade phase was constructed using three rows of posts, with some thickening in the middle where paired posts were used. The remaining 50 metres of palisade (east of the western limit of excavation on the south side of the village) overlapped with both the Phase 1 and 2 palisades.

This third and final phase of palisade construction also involved the addition of a palisade trench that extended across the northern, eastern and half of the southern boundaries of the site (Figure 5). This trench feature was not continuous and was broken up into several sections (Features 55, 85, 146, 709). After its excavation, this borrow trench was filled in with refuse, which justifies its characterization as a “trench midden” (see Section 2.6 below). Features 709 and 55 represented a virtually continuous trench around the northern half of the site. Approximately one-third of the way along the east side of the village there was a break in this trench corresponding with the area where the second and third palisade lines diverged. This area may have served as an entrance complex throughout the occupation of the site (see Section 2.3.2 and Figure 5). The trench then resumed as Feature 85, which was comprised of five sections separated by short breaks (but these may have joined together to form a single trench above subsoil level). There was a 45-metre stretch of trench adjacent to the section of palisade that formed the southeast corner of the site. The fact that there were breaks in this trench where the second phase palisade met the third phase palisade is significant, and may suggest that both palisades existed contemporaneously, if only for a short time.

Profiles of the trench feature/trench midden (see below) indicate that it extended to a depth of 15 to 25 cm below the subsoil. Given the removal of overlaying plough-disturbed soils, this indicates that the original trench may have been dug to a depth of approximately 50 cm and should not be considered to have been a defensive structure. Instead, this feature can be best interpreted as a borrow trench from which soil was excavated and used to build a strengthening embankment at the base of the palisade. The Aurora site, which was one of the successor villages to Mantle (Birch and Williamson 2013), was also described as having an earth ring or embankment, and was originally named “The Old Indian Fort Site” (Emerson 1954:165).

## **2.4.2 Palisade Entrances**

In each palisade phase there were a number of possible palisade entrances (PE) to the village. Since some may have persisted through all phases of occupation, PEs are discussed here starting with the northern side of the village and proceeding clockwise around the enclosure.

### ***Palisade Entrance 1***

A possible entrance to the village was situated on the northern side of the village, approximately 75 metres east of the western limit of excavation and five metres north of the east end of House 1 (Figure 39). This possible entryway was associated with Palisade Phases 1 and 2, or the early phase of village occupation (Figure 6). This opening was 2.5 metres wide and was oriented 71.5 metres east of north. Seven metres to the east of this possible entrance was a wall that connected House 1 to the palisade, and may have been constructed to restrict access to the eastern portion of the village from this point of entry.

### ***Palisade Entrance 2***

Just south of the northeast corner of the Phase 1 and 2 palisades was a gap that may or may not have been a point of entry to the village (Figure 6 and 40). It was approximately 13.5 metres in width and was located adjacent to the northeast wall of House 26. Fifteen single and paired posts within this gap suggest that it was the result of poor post preservation and not an actual entrance. The “ragged” nature of the sides of this gap supports this interpretation.

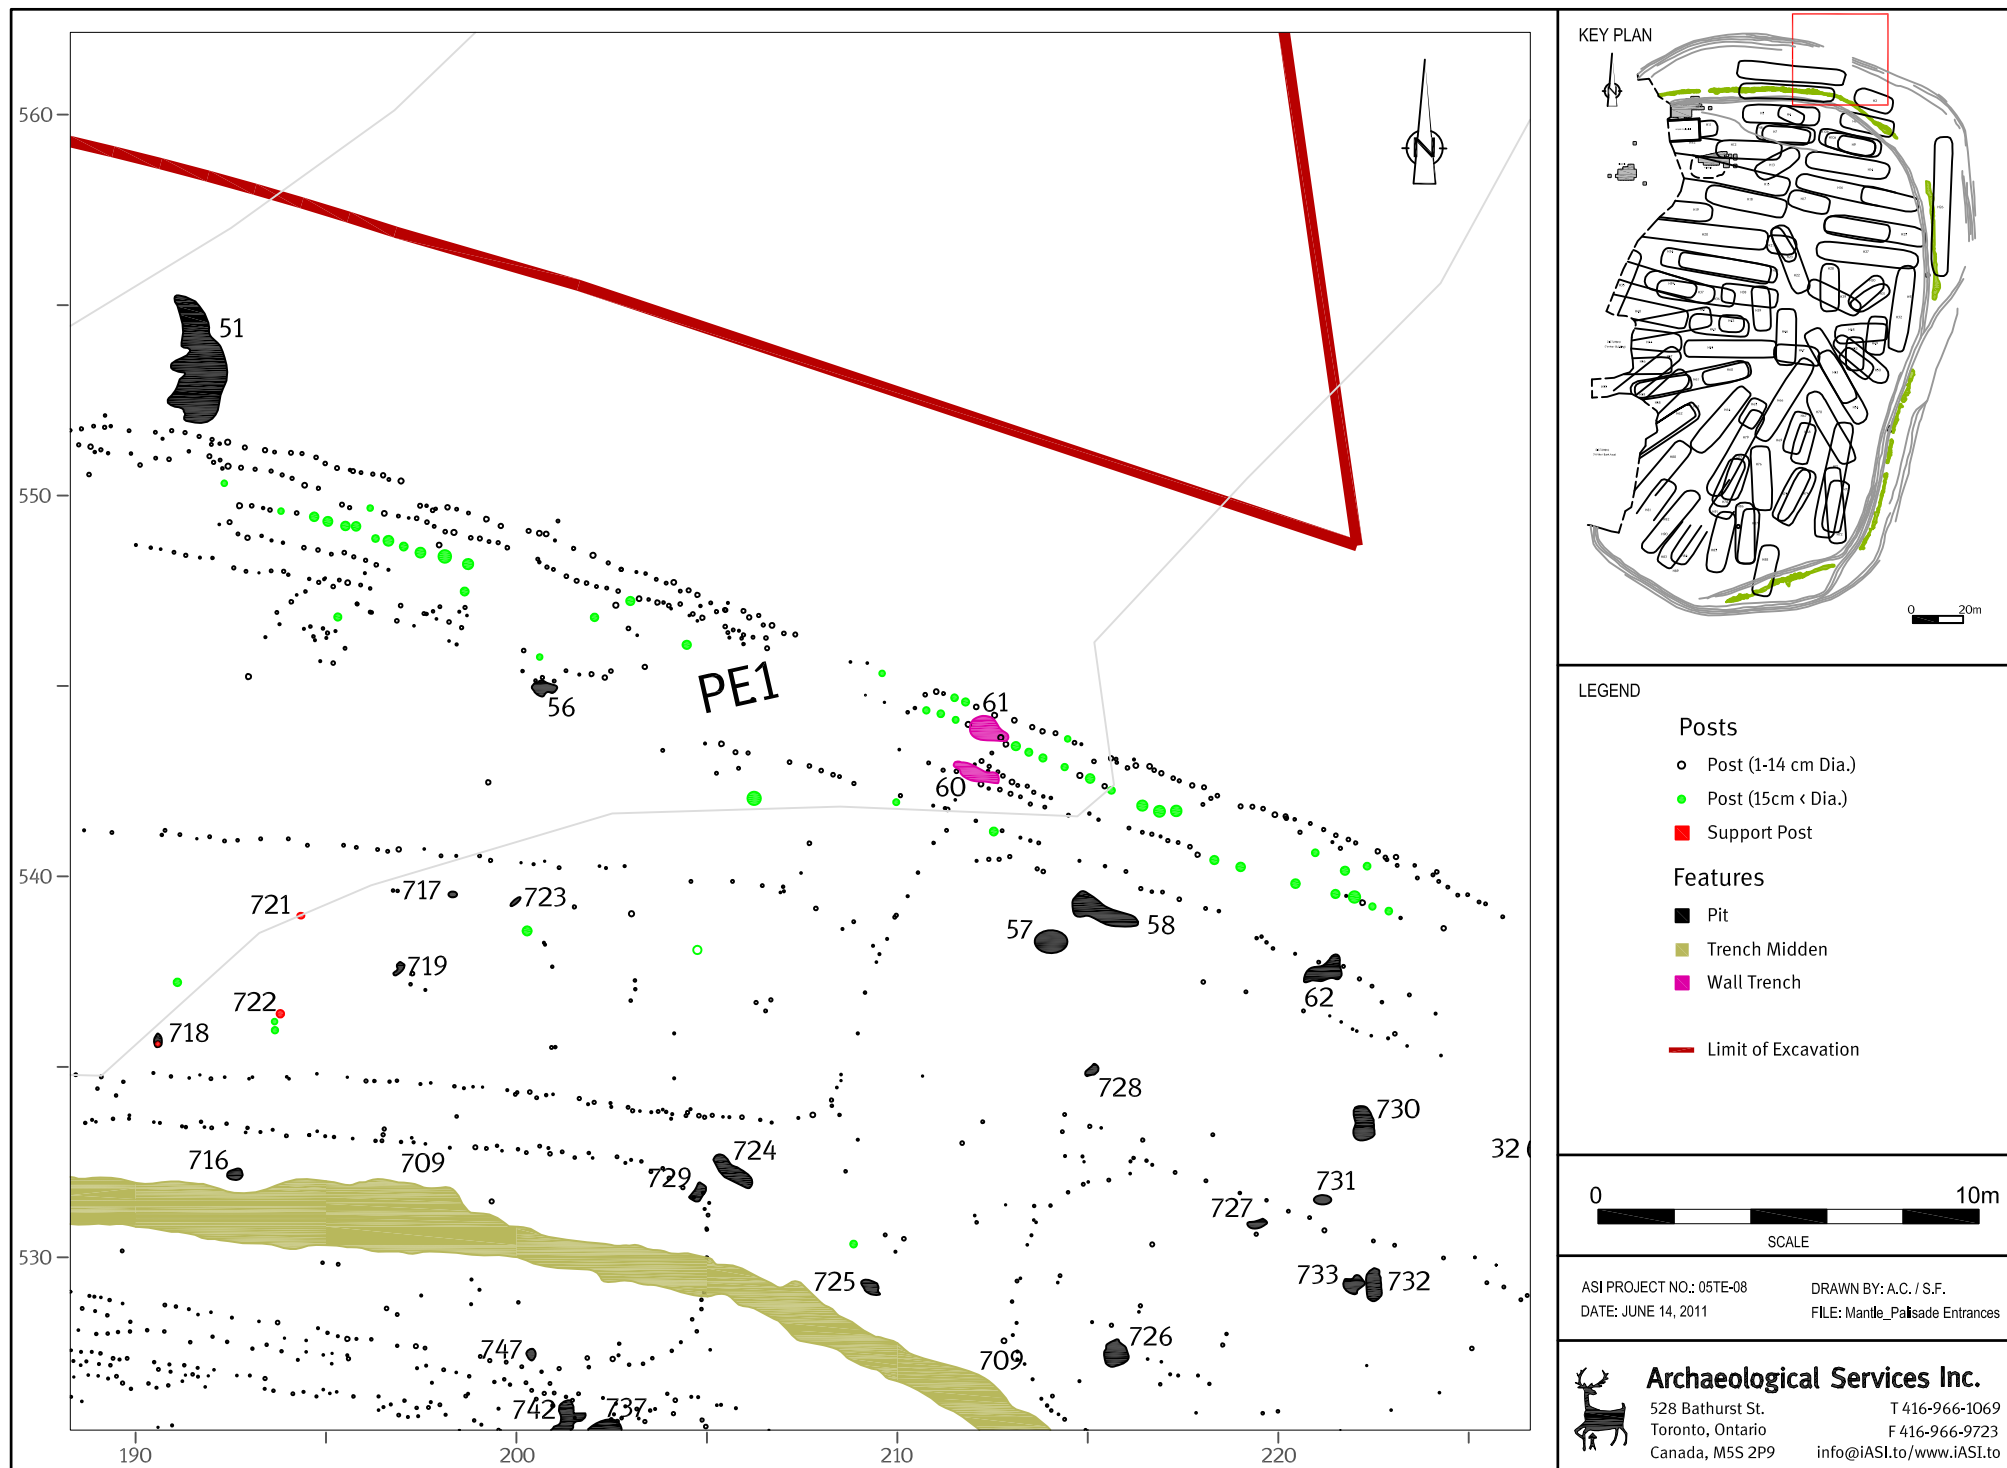

Figure 39: Palisade Entrance 1

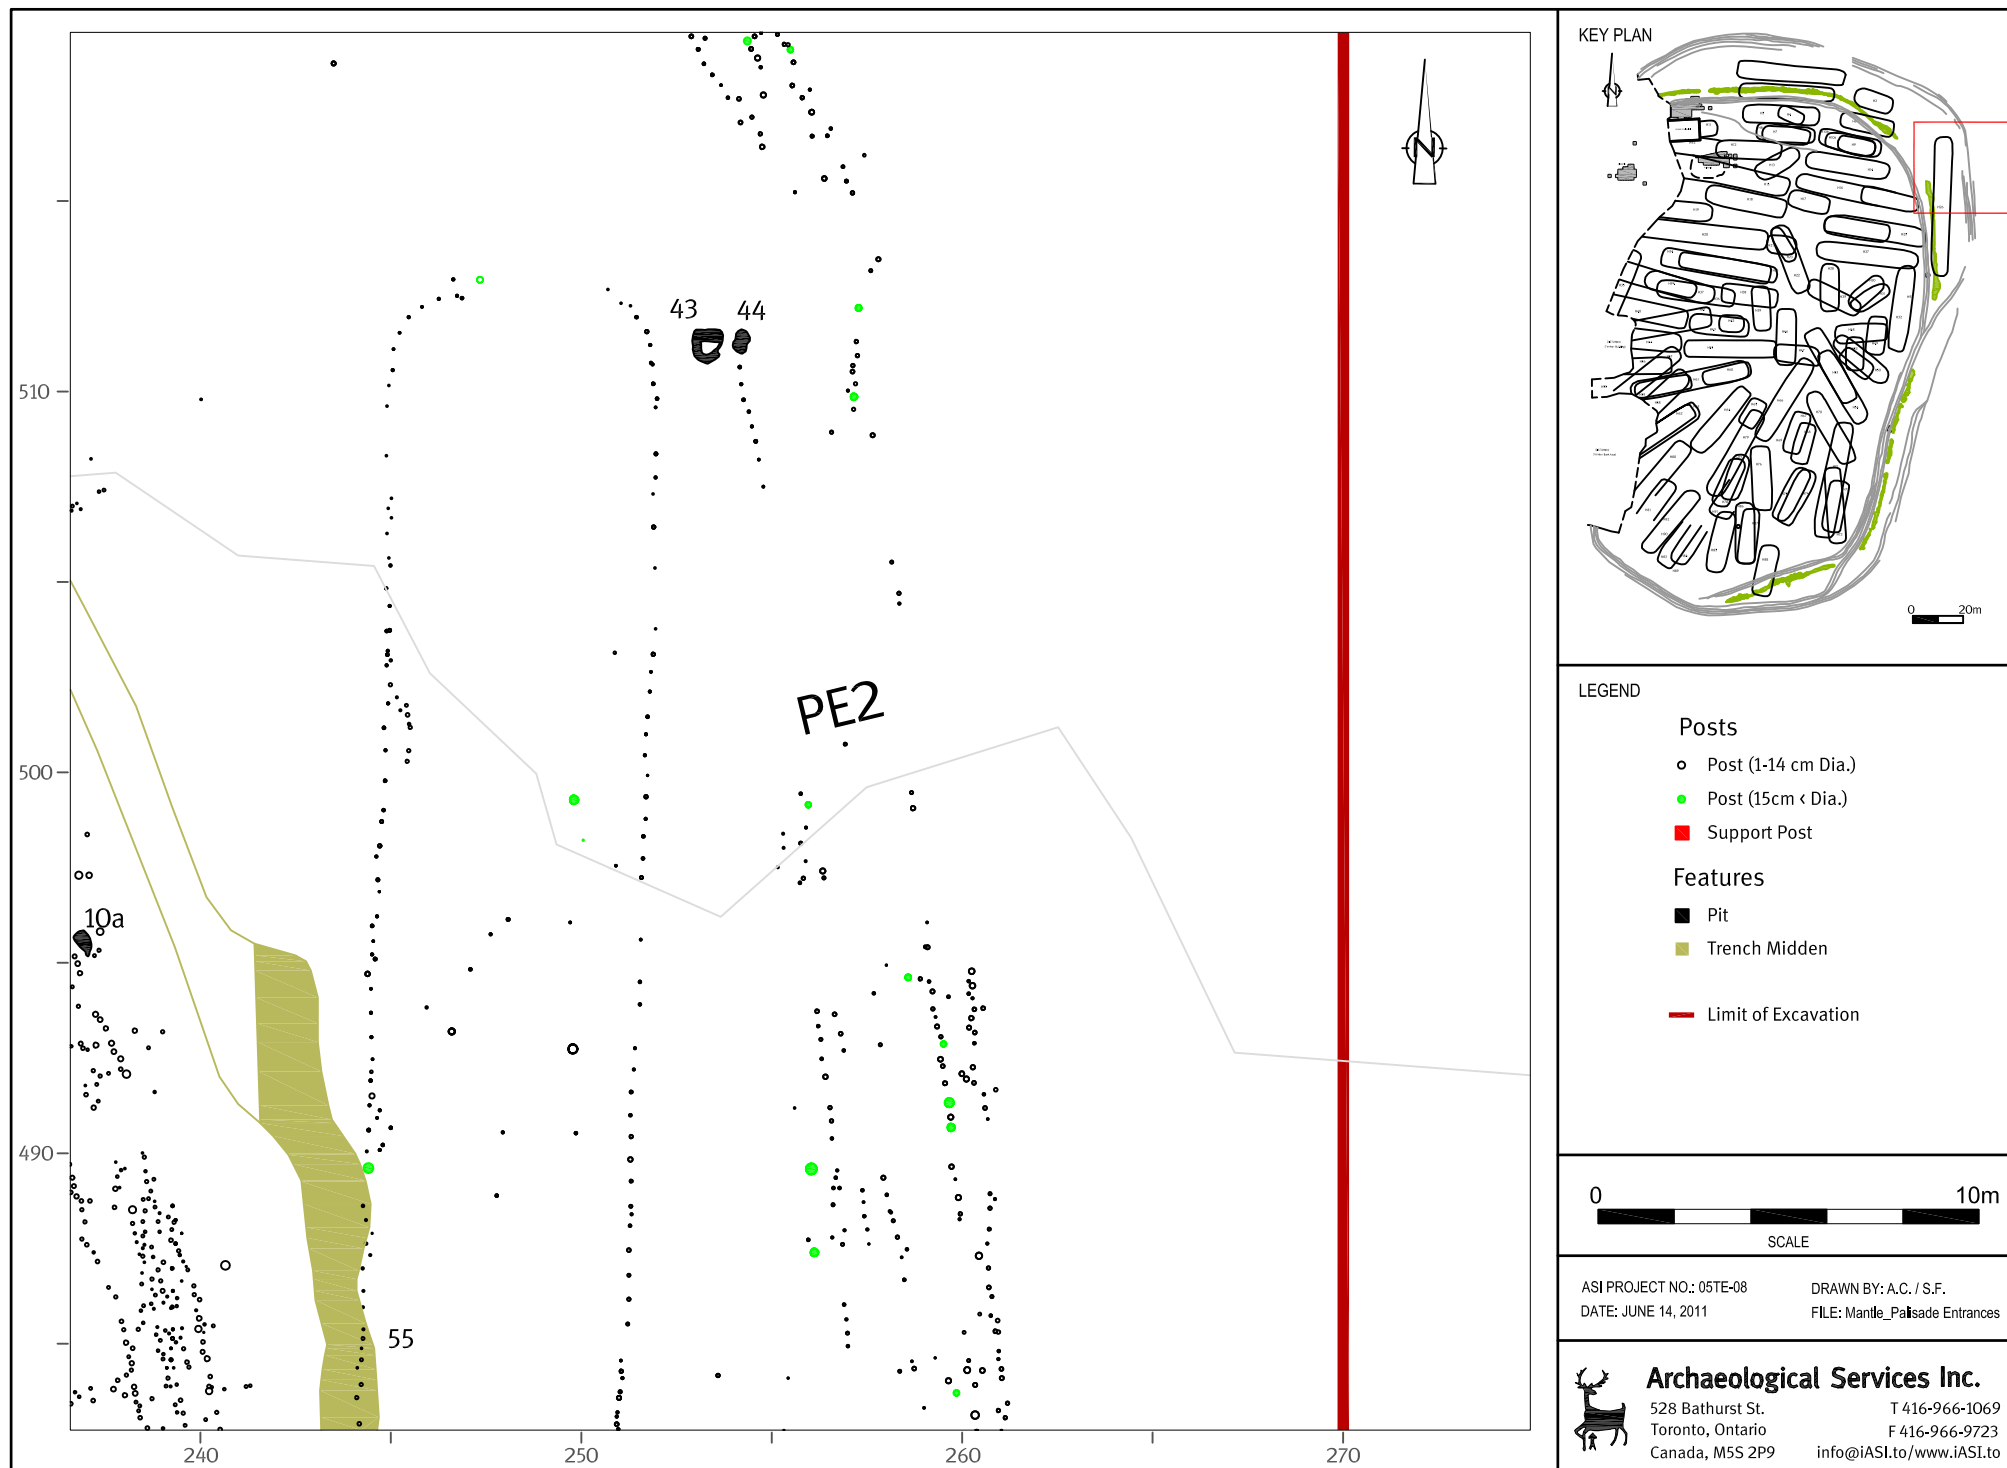

Figure 40: Palisade Entrance 2

### ***Palisade Entrance 3 - Entrance Complex***

PE3 is a complex of entrances that appears to have persisted throughout the occupation of the village.

**Palisade Entrance 3 – Early Phase:** In the first phase of palisade construction there appears to have been an entrance that was 28 metres in width (Figures 6 and 41). On the north side of this opening the palisade overlapped with the Phase 2 palisade, and appears to have been constructed using two or more rows of posts. South of this entrance the Phase 1 palisade was constructed using a single row of posts. There was one hearth feature (Feature 41) in the centre of this entrance, which may have been significant in terms of protecting this wide opening from unwanted animal or human intruders.

In the second phase of palisade construction, but still part of the early phase of village occupation, the northern edge of this entrance remained in the same position. The southern edge was contracted, resulting in a smaller entrance that was approximately 12 metres in width. These two entrances are the largest gaps identified in the palisade, notwithstanding the possibility of other large entrances in the unexcavated and/or disturbed western side of the village (Figure 5). These large entrances to the village would have permitted rapid access to the open plaza area that occupied the east-central portion of the village in the early phase of occupation (Figure 6).

**Palisade Entrance 3 – Late Phase:** In the third and final phase of palisade construction, both the palisade and this entrance were contracted. This entrance was tapered, with a 6.5 metre wide opening on the outside of the palisade, narrowing to three metres inside. Immediately adjacent to this entrance were two late phase structures, Houses 27 and 32 (see Figures 18, 19 and 41). The east and north ends of these houses were placed such that there is no way to pass between them into the village. People using this entrance in the late phase of the village's occupation would have had to go around these houses in order to gain entry to the village.

The continuity of these three entrances through all phases of occupation suggests that this area may have formed an “entrance complex”. Residents and visitors to the village may have viewed this area as a key point of access through the palisade.

### ***Palisade Entrance 4***

PE4 was located 23.5 metres south of the late phase PE3 along the Phase 3 palisade (Figure 5). This entrance overlapped with two to three rows of the earlier Phase 2 palisade. In the third phase this area was opened up, leaving a gap of four metres. This entrance was also directly adjacent to the late phase House 32 (Figures 19 and 42).

### ***Palisade Entrance 5***

PE5 was in the second phase of palisade construction in the southeast corner of the village, and it was relatively narrow (2.5 metres in width) (Figures 5 and 43). There were two hearths (Features 83 and 89) immediately north and adjacent to this entrance, which, together with hearth feature 41 situated in the middle of the phase 1 PE 3, suggests that there may have been some association between hearths and palisade entrances (Appendix B). This entrance would have provided access to the early to middle phase houses in the southern portion of the village.

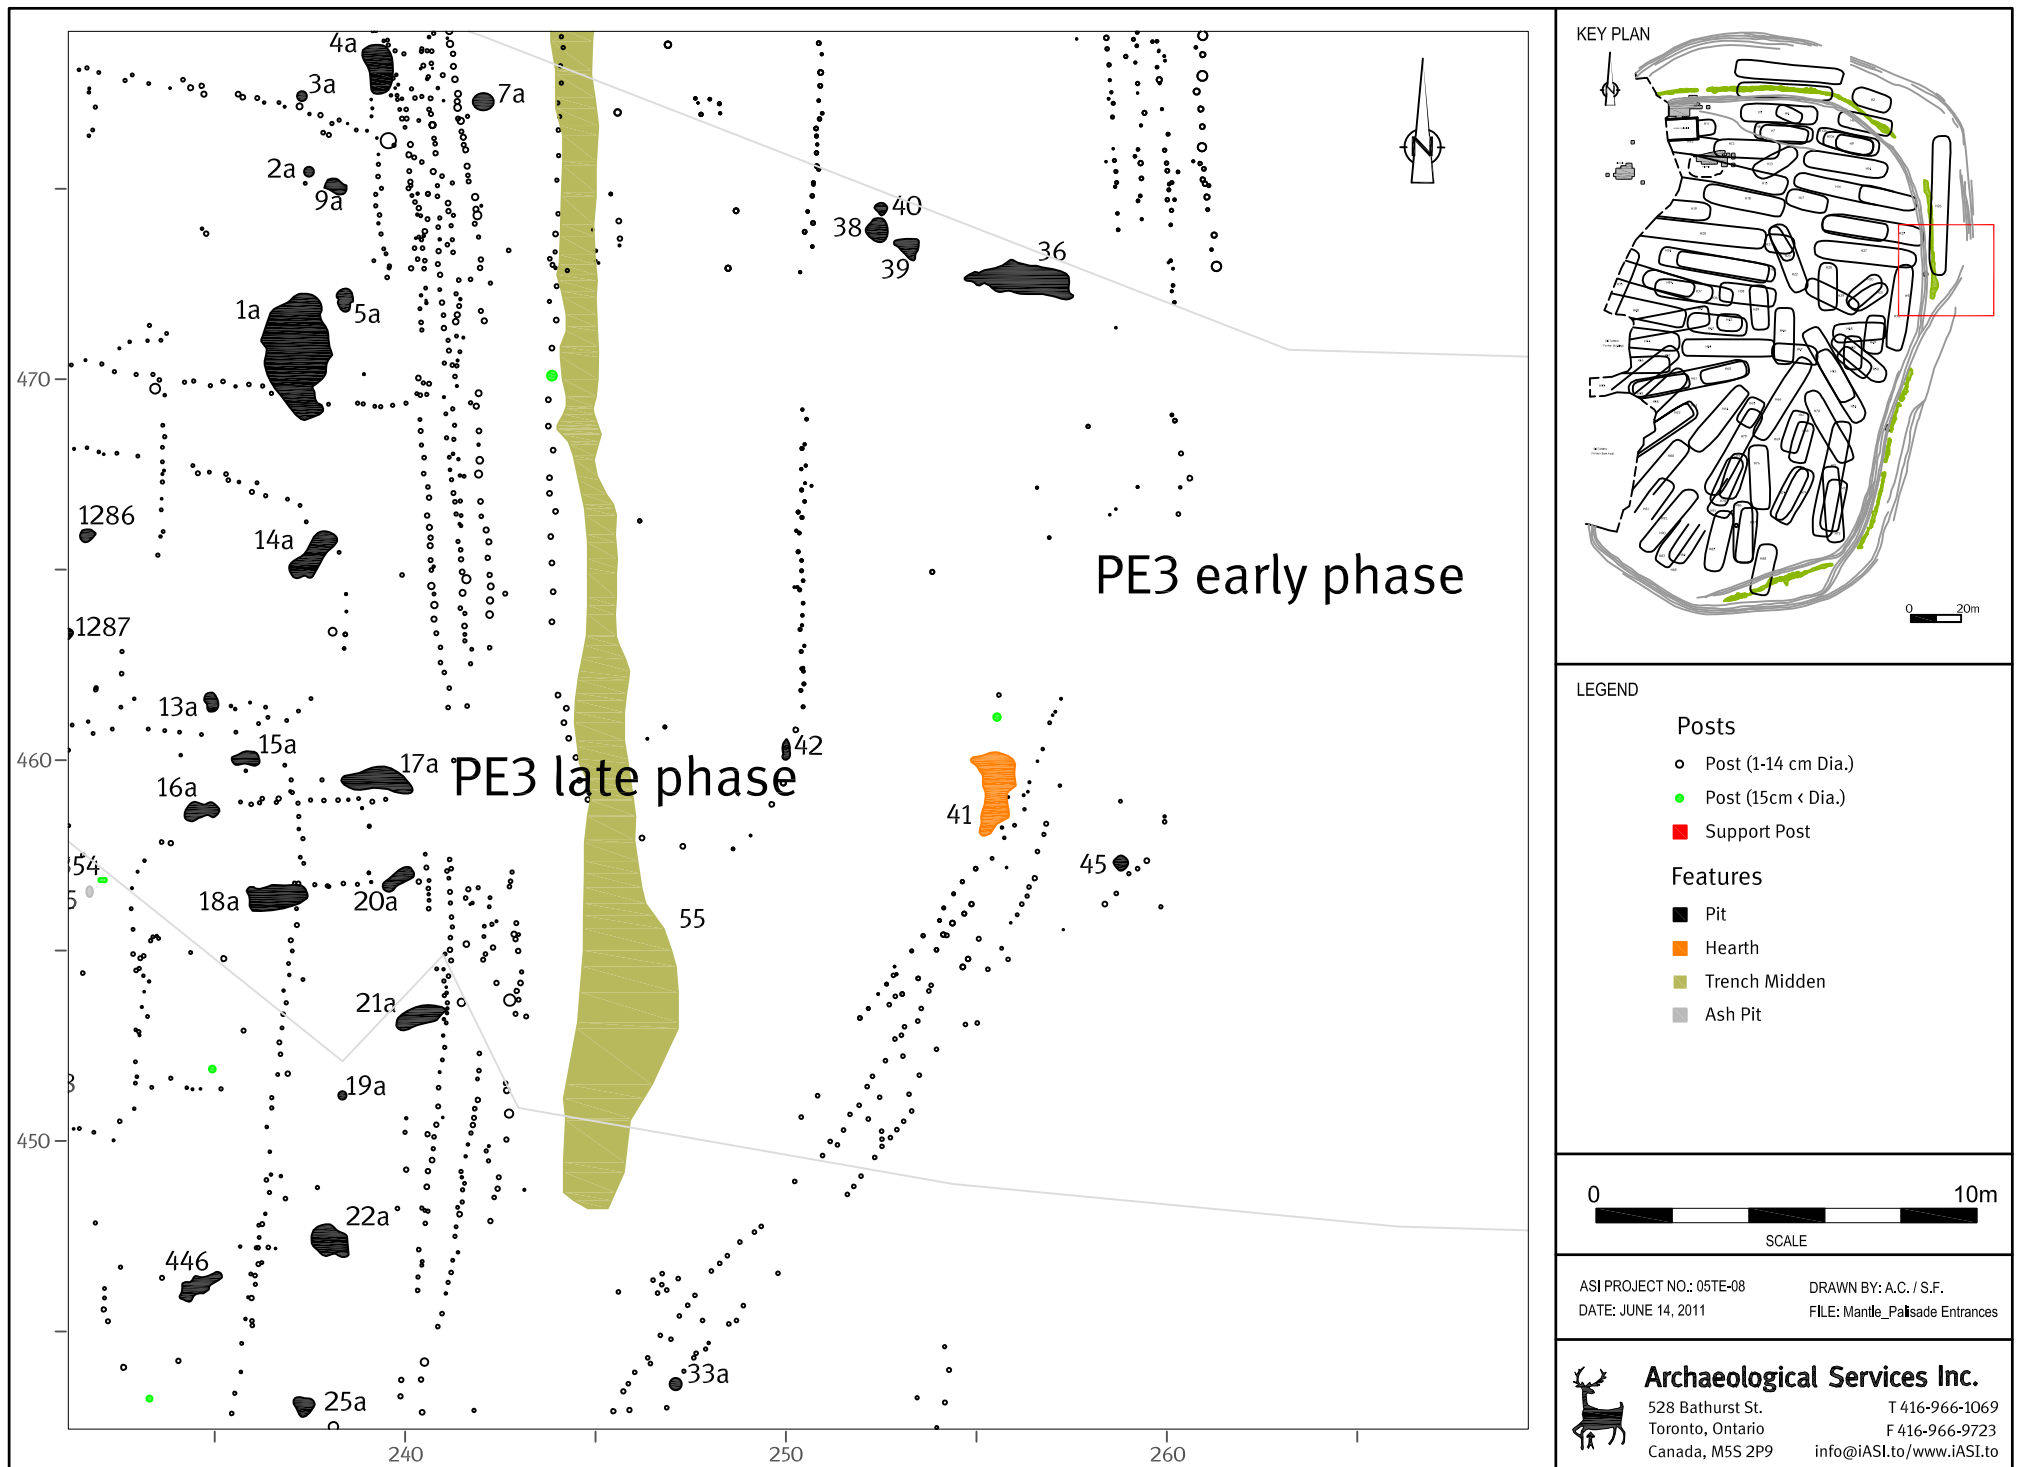

Figure 41: Palisade Entrance 3 - Early and Late Phases

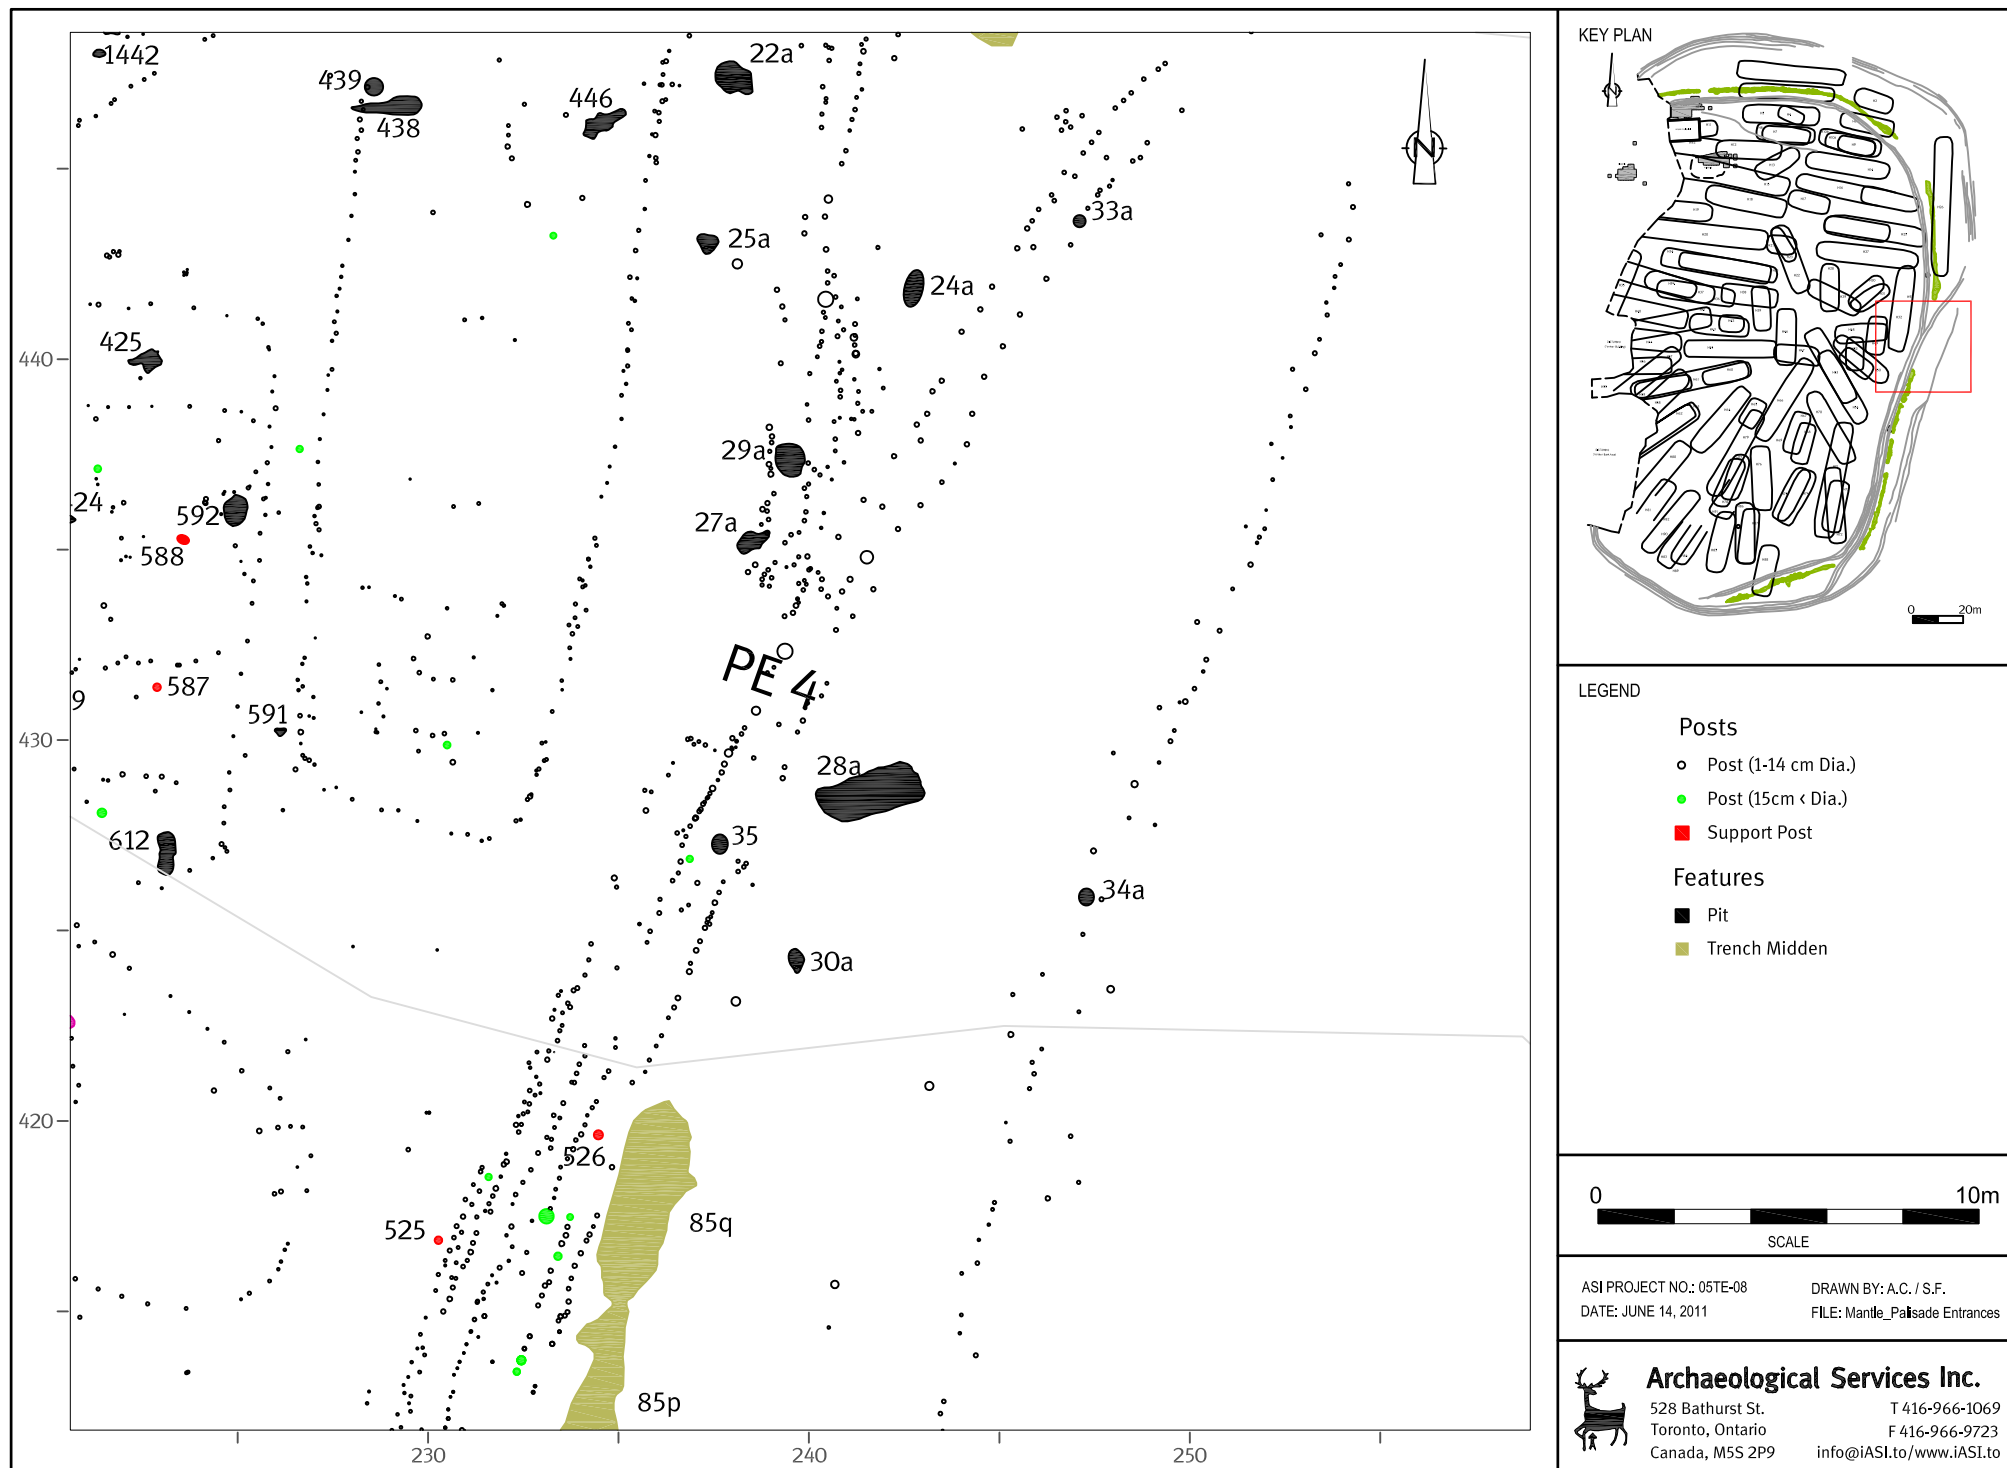

Figure 42: Palisade Entrance 4

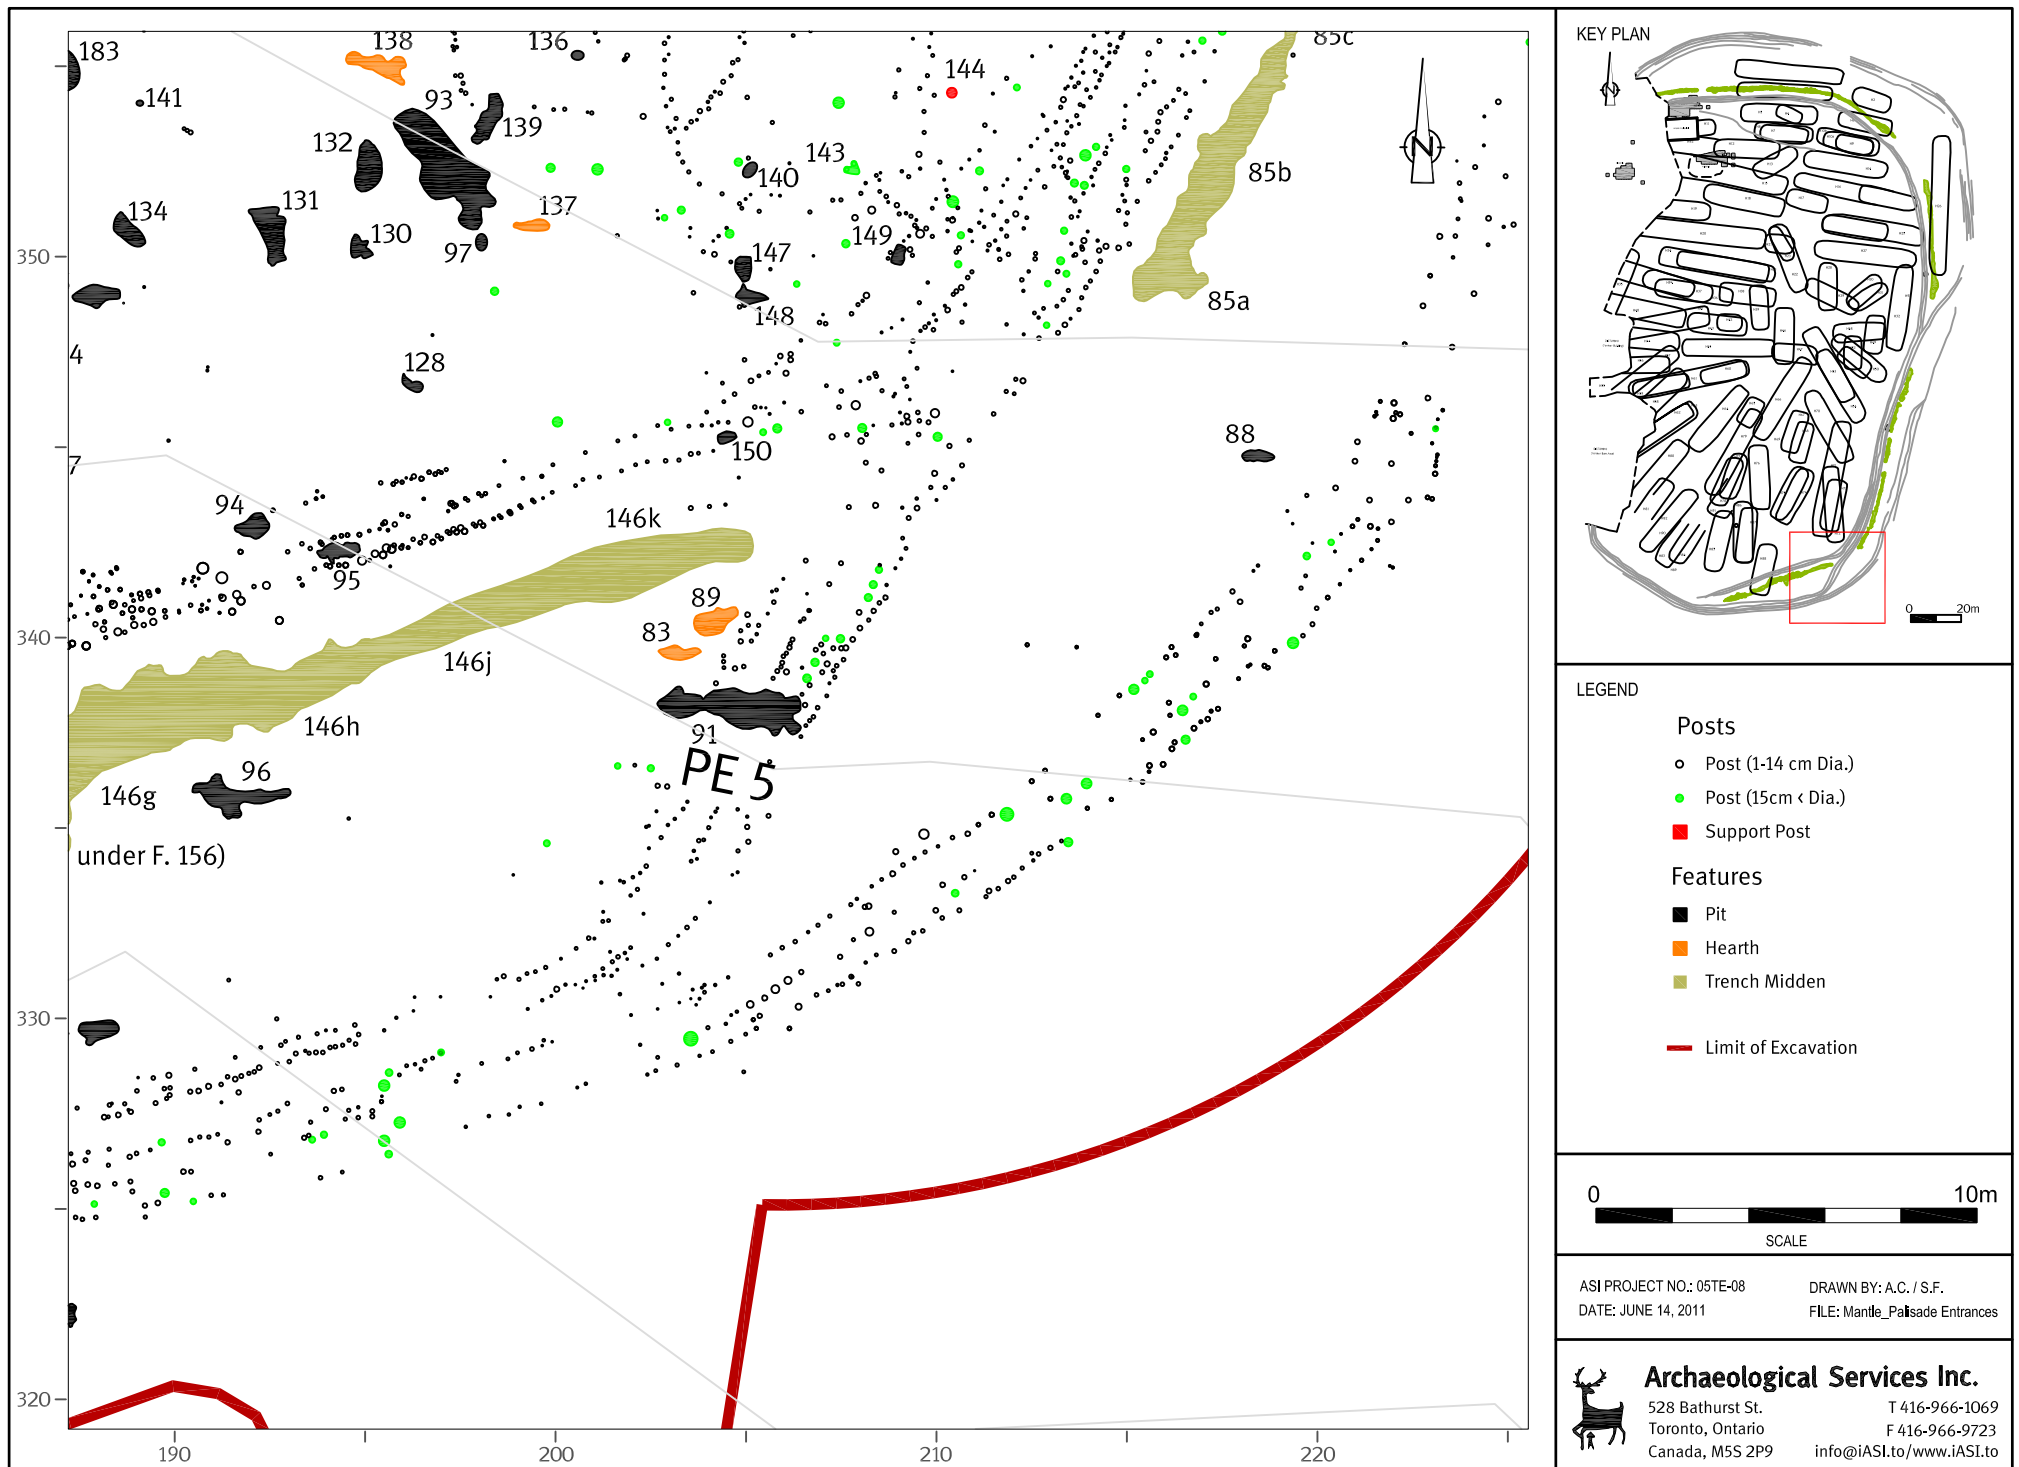

Figure 43: Palisade Entrance 5

### **Palisade Entrance 6**

Palisade entrance 6 was located at the southernmost point in all three palisade phases (Figures 5 and 44), and it appears to have been in place throughout the occupation of the village. This entrance was also relatively narrow (approximately two metres in width) with straight sides and no tapering. It would have provided access to the houses in the complex southern portion of the village.

### **Palisade Entrances 7 and 8**

PE7 and PE8 were located on the east side of the village and were associated with the third phase of palisade construction (Figure 45). There is some uncertainty as to whether or not these possible palisade entrances are actual gaps in the palisade or if they had been negatively impacted during excavation.

PE 7 was two metres in width and PE 8 was three metres in width. Both also included gaps of an equivalent width in the palisade trench before each entrance. These gaps in the palisade were located 11 metres from the late phase House 70 (Figure 23). If these were true entrances to the palisade they would have provided access to the southeast portion of the village.

### **2.4.3 Fence line**

A 47 metre long row of posts crossed the northern portion of the site on a meandering, roughly northwest to southeast orientation (Figure 5). We have designated this feature of the settlement plan a “fence line,” but its actual purpose or function is unknown.

The easternmost portion of this fence line was composed of 11.5 metres of paired posts. After this stretch, it dipped slightly south and became a line of single posts. This single line continued to the end of the fence, although there was a dense cluster of posts two metres in length located approximately four metres from the end of the fence. The fence line crossed (from west to east) Houses 95, 8, and 7 (Figure 5). It was located on the highest point of land at the site immediately adjacent to the northeast end of House 12 and the northwest end of House 13. It is possible that it was built prior to the construction of the palisade to serve as a windbreak. If this was the case, it would have been contemporary with House 13, and may have been built by the initial group sent to prepare the site for settlement. It is also possible that it was associated with activities at the site predating the village.

## **2.5 Activity Areas**

### **2.5.1 Plaza**

In the early phase of the village there appears to have been an open space left in the centre of the village that was surrounded by a ring of parallel and radially aligned houses (Birch and Clish 2009; Birch 2010:122-123) (Figure 6). It is possible that this area was used as a plaza.

The longest houses appear to have been those that were the most frequently rebuilt or maintained. Houses 15 and 20, for example, both estimated to have exceeded 50 metres in length, had wall post densities of 6.8 and 7.9 posts per metre, respectively. Conversely, many of the smaller houses at the site (those less than 30 metres in length) had very low post densities.

When short, superimposed houses with very low wall post density are removed from representations of the early and late phases of the village plan(s), an open area emerges in the east-central portion of the site (Figure 6). There were two clusters of houses in this area – Houses 28, 29, 30 and 31 and Houses 47, 48,

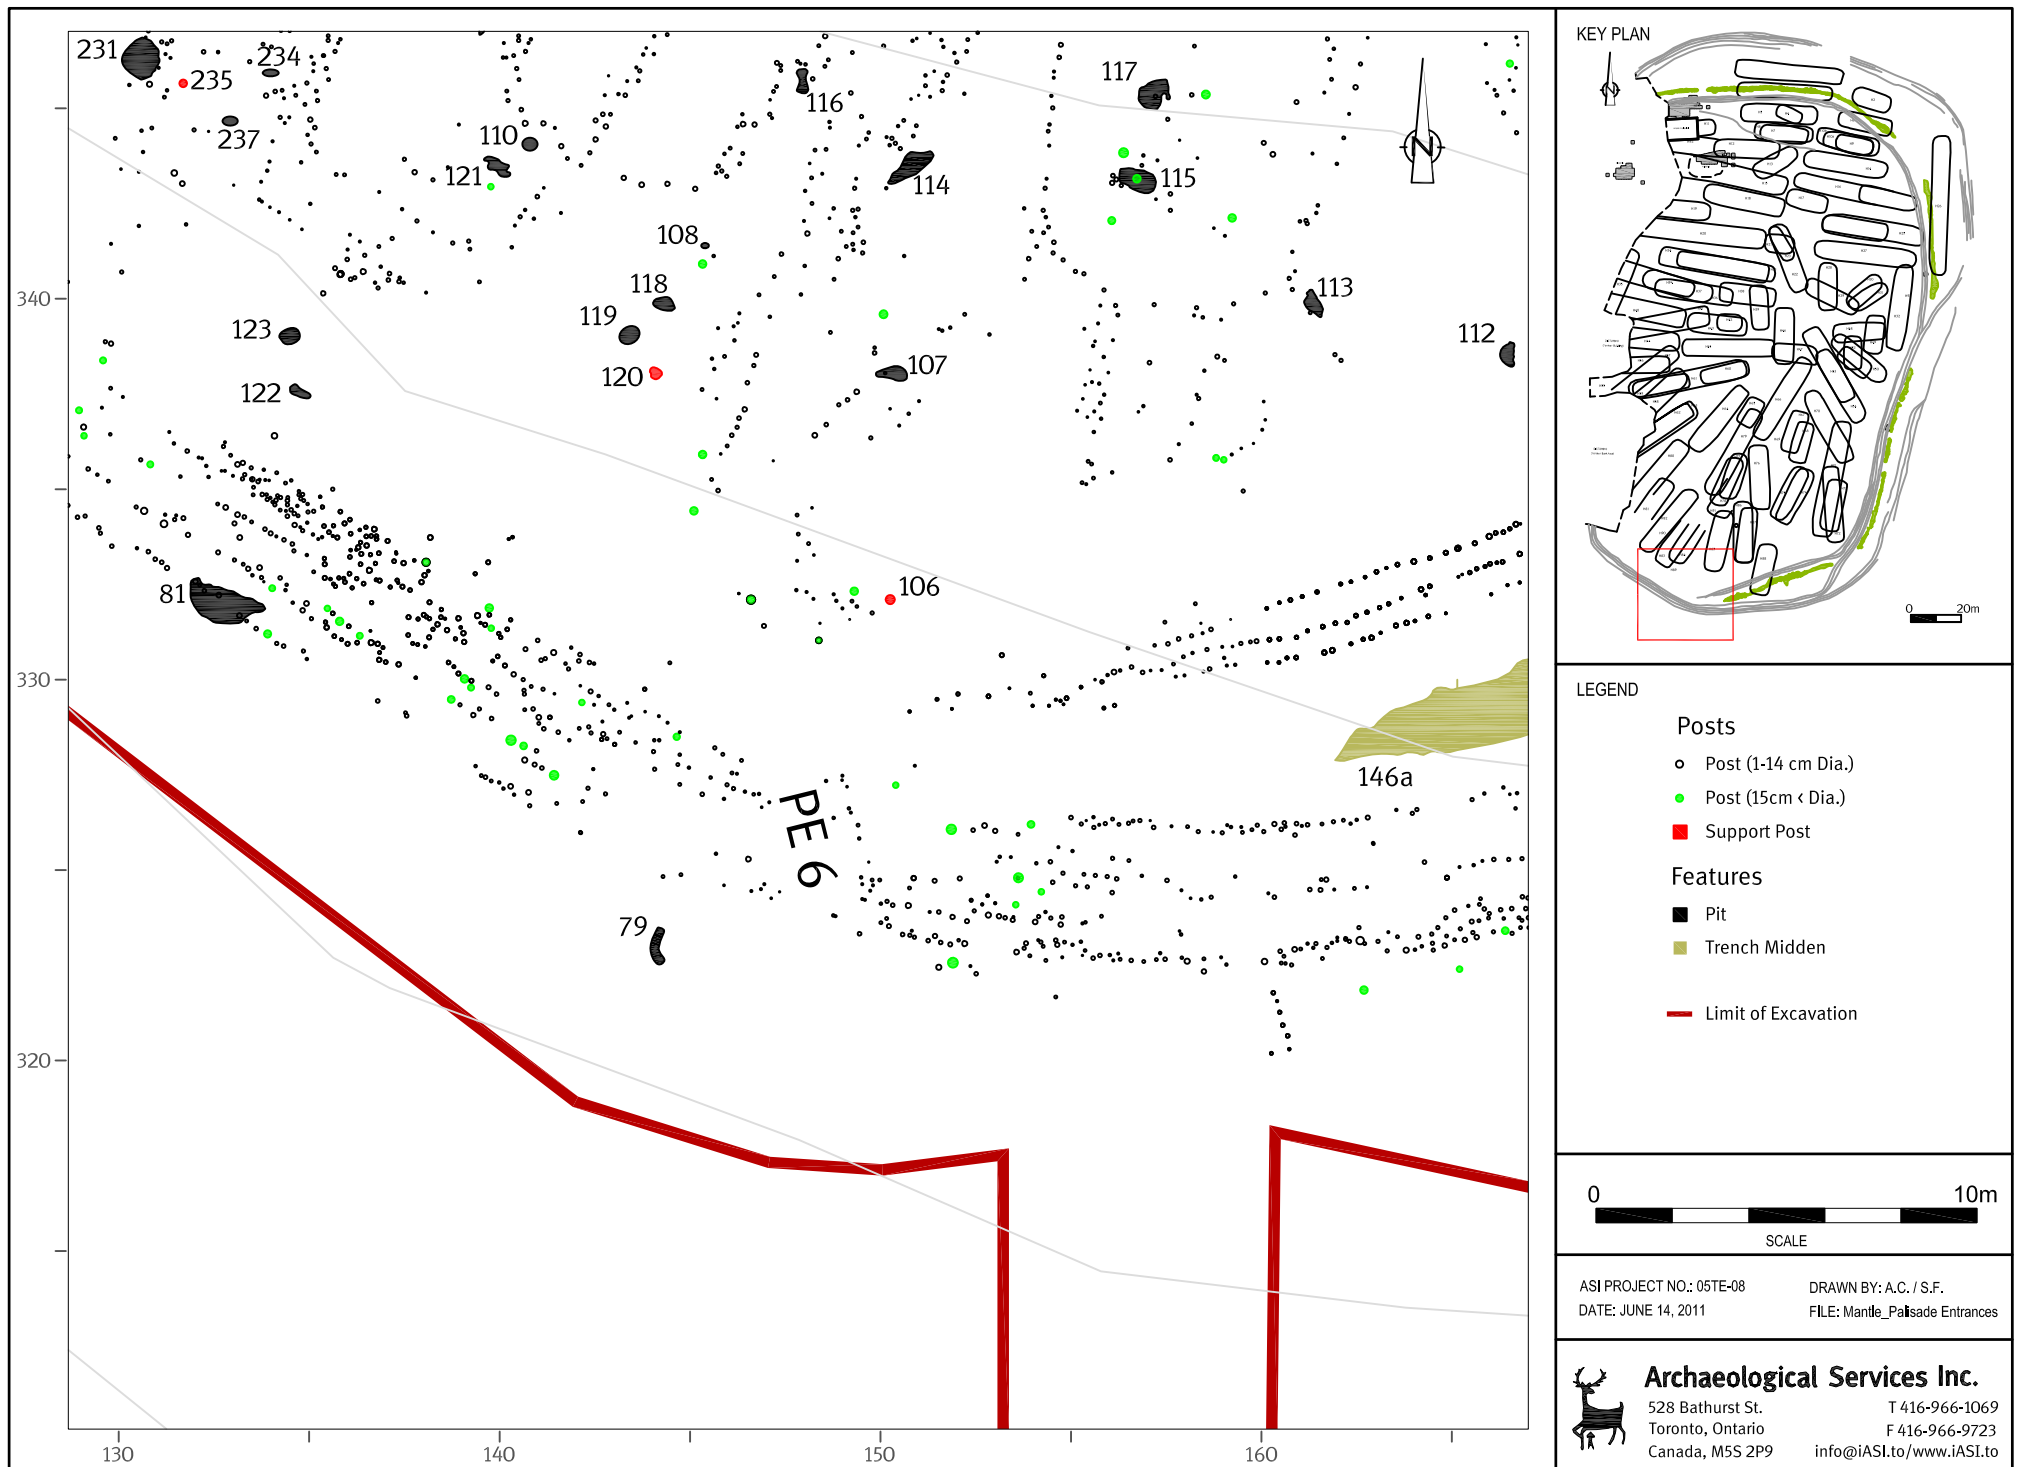

Figure 44: Palisade Entrance 6

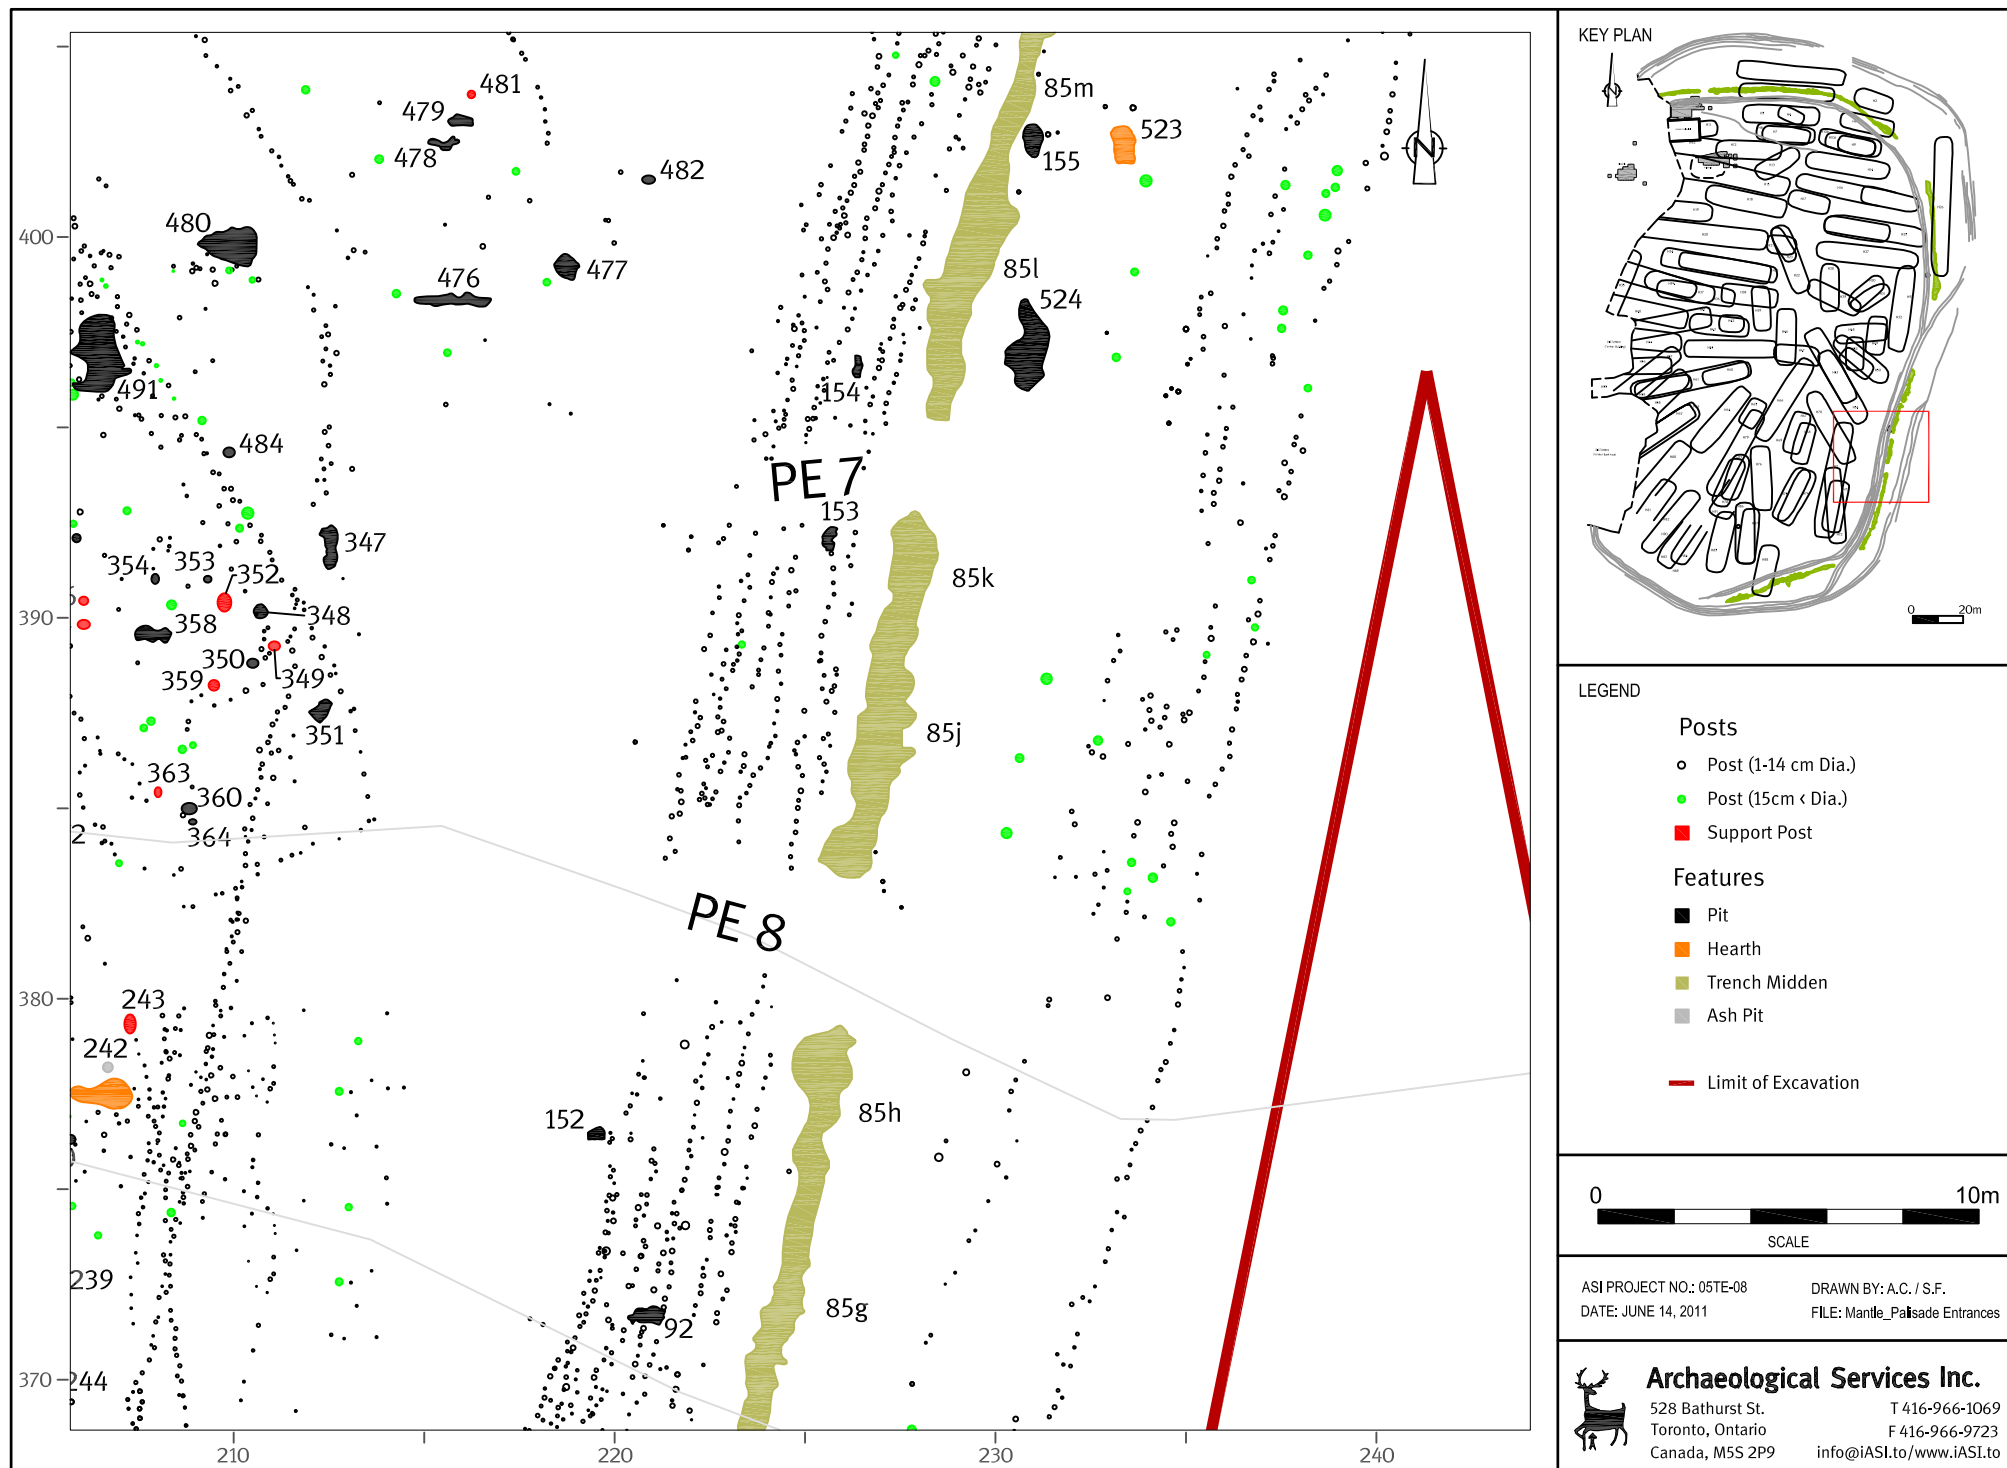

Figure 45: Palisade Entrance 7 and 8

49, 50, 51 and 52 – in which houses were constructed, dismantled and replaced multiple times during the occupation of the village. The wall post densities of these structures were quite low, on average less than 3.5 posts per metre (Table 1). While these structures may have served an important function while in use, it is also possible that some were temporary or seasonal structures and were relatively short-lived within the early phase of occupation. In the case of the houses in the two clusters listed above, even if one of these structures was constantly in use, a significant amount of empty space would have existed.

The existence of many features in this central area also supports the idea that this area was a plaza. These features included large refuse and ash-filled depressions (Features 427, 429, 568, 569 and 1324), which could have been related outdoor activities carried out in the plaza (Figures 25 and 46 and Appendix B).

This plaza at the centre of the site could have served as a socially integrative space (Lipe and Hegmon 1989; Rautman 2000). It would have provided a venue for communal events such as feasts and ceremonies, and also increased visibility between houses in the village as people went about their daily domestic tasks. Whether these longhouses represent migration to the village or reorganization of existing residents is unknown.

In the late phase of occupation, this space was filled in with new houses (Figure 7). This re-organization of the village plan may have been related to the contraction of the village and the concomitant loss of space within the palisaded village precinct. For further discussion of this plaza and its role in the history of the Mantle community, see Birch 2010 and Birch and Williamson 2013.

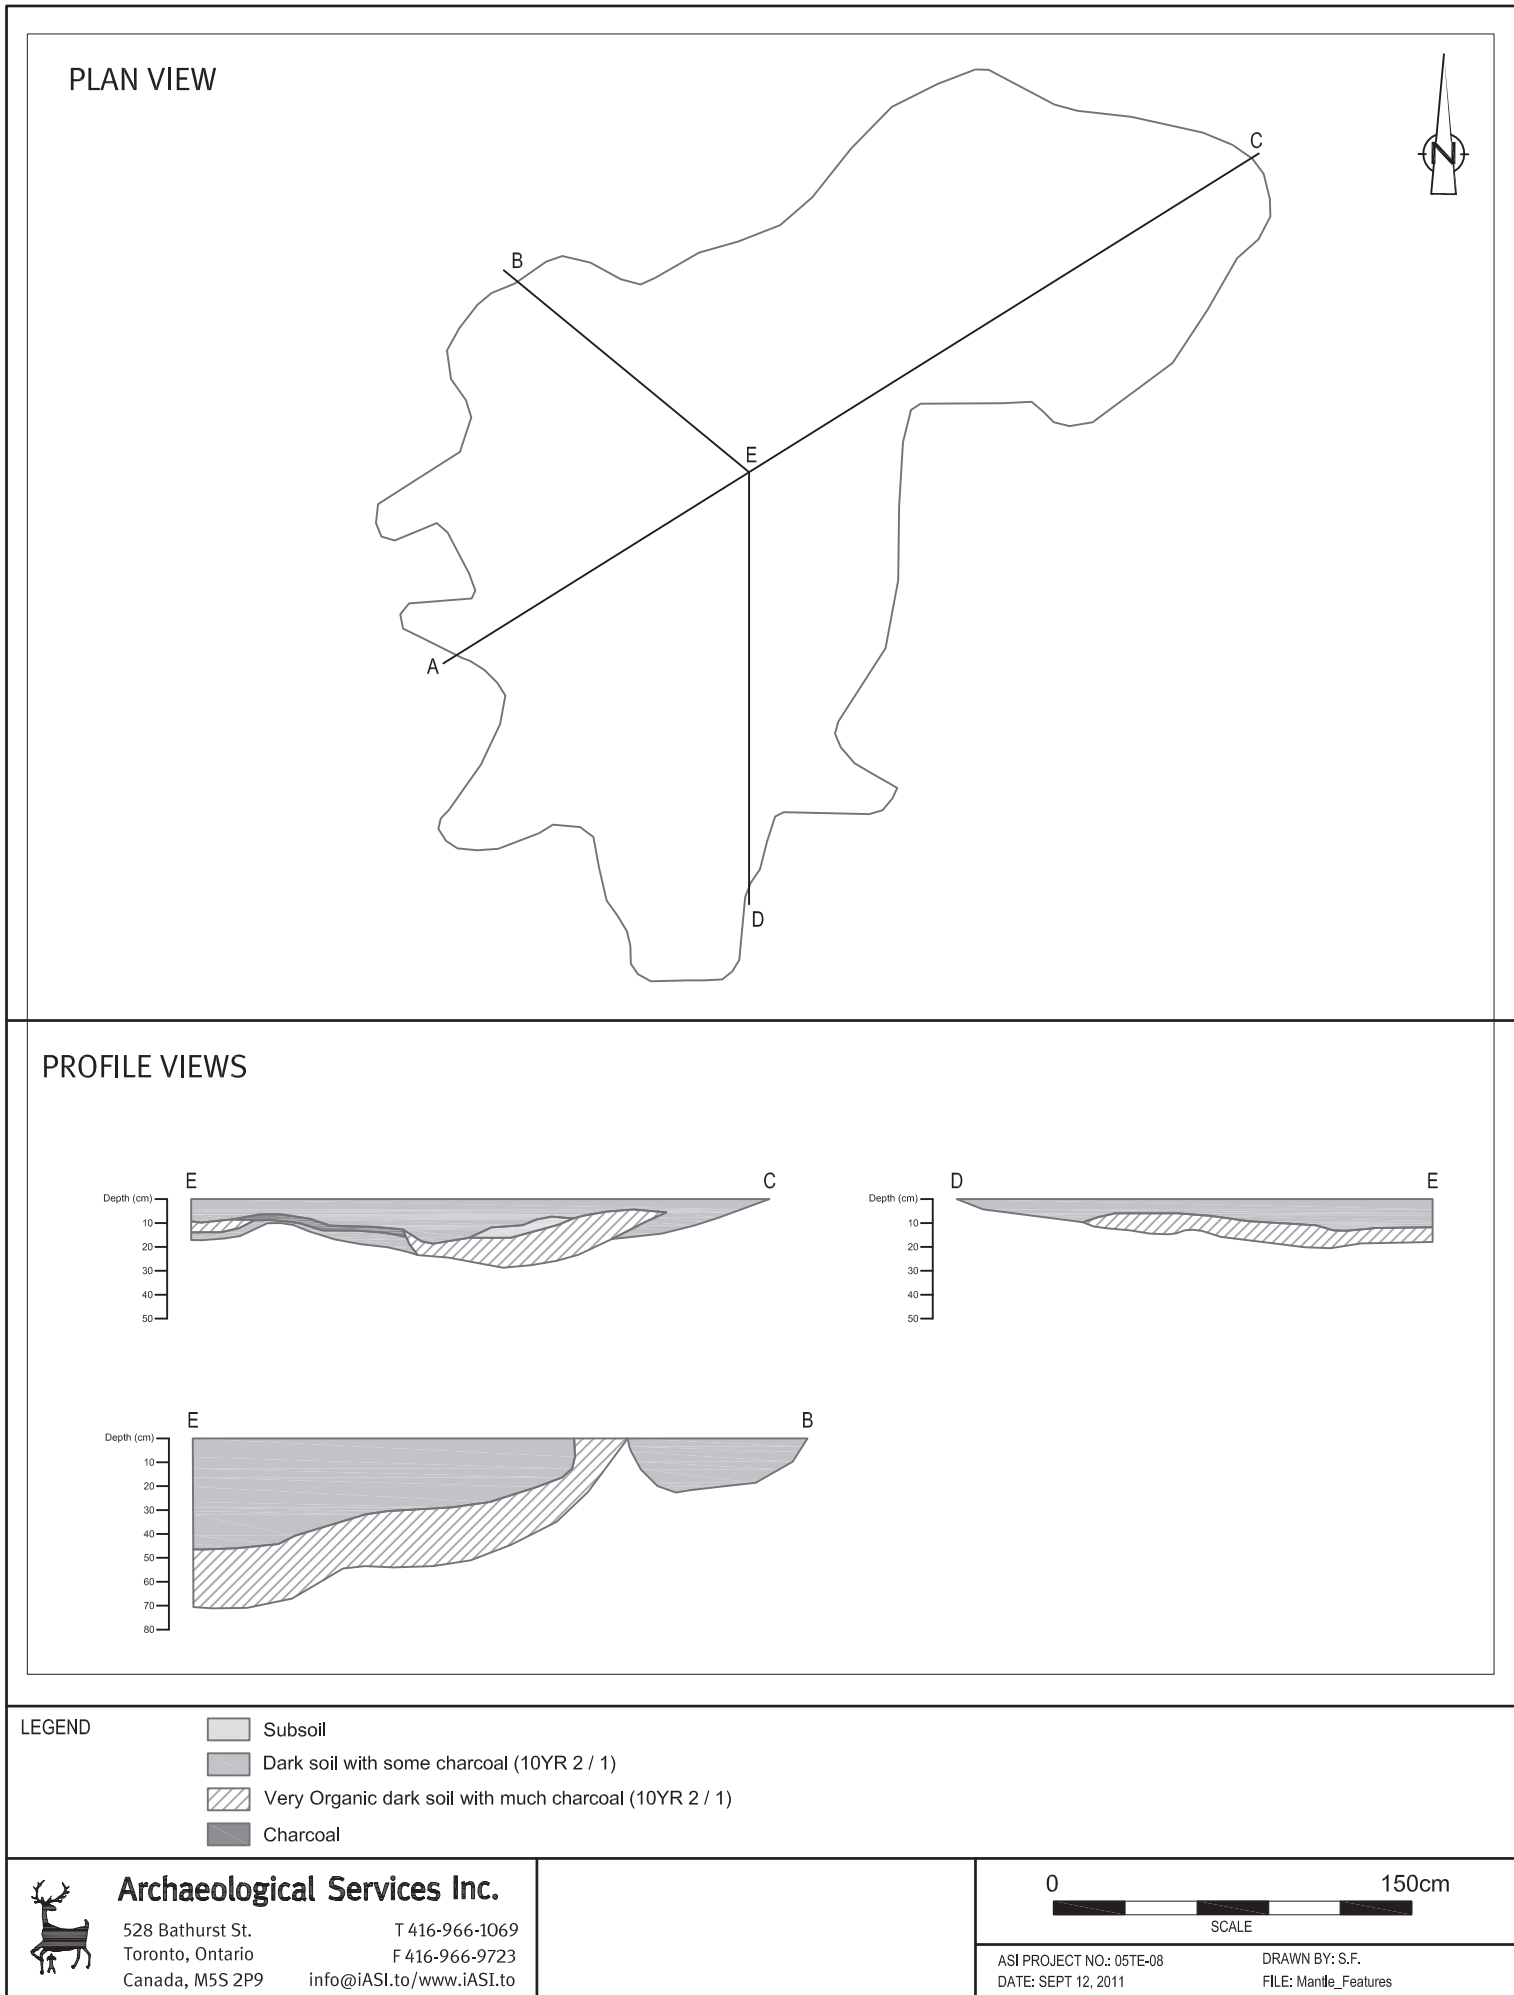

Figure 46: Plan and Profile View of Feature 429

## **2.5.2 Exterior Activity Areas**

Due to the substantial amount of overlap between houses and exterior activity areas in both phases of the occupation of the village, it was difficult, and in some cases impossible, to associate particular features with either houses or exterior activities. Only those exterior activity areas (EAA) with particularly dense or notable concentrations of features and/or hearths are discussed below.

### ***Exterior Activity Area 1***

EAA1 was utilized during the late phase of village occupation, as many of the features included in EAA1 overlapped with the first and second palisade phases and the early phase of occupation. This area was located approximately 22 metres north of the northern limit of the third palisade phase (Figure 47). It included (from west to east) Features 67, 50, 69, 54, 53, 70, 63, 65, 68 and 51 (Appendix B). Hearth feature 59 was situated at the approximate centre of this cluster of features, which covers approximately 505 m<sup>2</sup>. The purpose of this exterior activity area is unknown; however, it is the only major activity area identified outside the palisaded village precinct that it is not directly accessible by any of the Phase 3 (late) village palisade entrances.

### ***Exterior Activity Area 2***

EAA2 was located in the space between Houses 18, 19 and 20, all of which were probably occupied for the full duration of the village (Figure 48). It consisted of a cluster of pit features (from counter clockwise: Features 1035, 1025, 1030, 1029, 1032, 1040, 1094, 1093, 1099, 1103, 1107, 1006 and 1072). Hearth feature 1047 lay approximately in the centre of this concentration of activity (Appendix B). There was a cluster of 19 posts located three metres east of Hearth feature 1047. Features 1097, 1100 and 1125, located 12 metres east of Hearth Feature 1047 should also be considered to have been part of this activity area. EAA2 covers 136 m<sup>2</sup> and is almost certainly the result of outdoor activities carried out by the occupants of Houses 18, 19 and 20 (Figure 15).

### ***Exterior Activity Area 3***

EAA3 was located between Houses 16 and 25 (Figures 15 and 49). It consisted of a cluster of pit features (from west to east, Features 1154, 1178, 1150, 1165, 1128, 1129, 1130, 1131, 1086, 1054, 1055, 1056 and 1058), two large posts (Features 1151 and 1059) and a refuse-filled depression (Feature 1173) (Appendix B). The total activity area covered 136 m<sup>2</sup>, and there were no hearth features present. Since this activity area was delimited by early phase Houses 16 and 25, it was probably associated with the early phase of occupation (Figure 6).

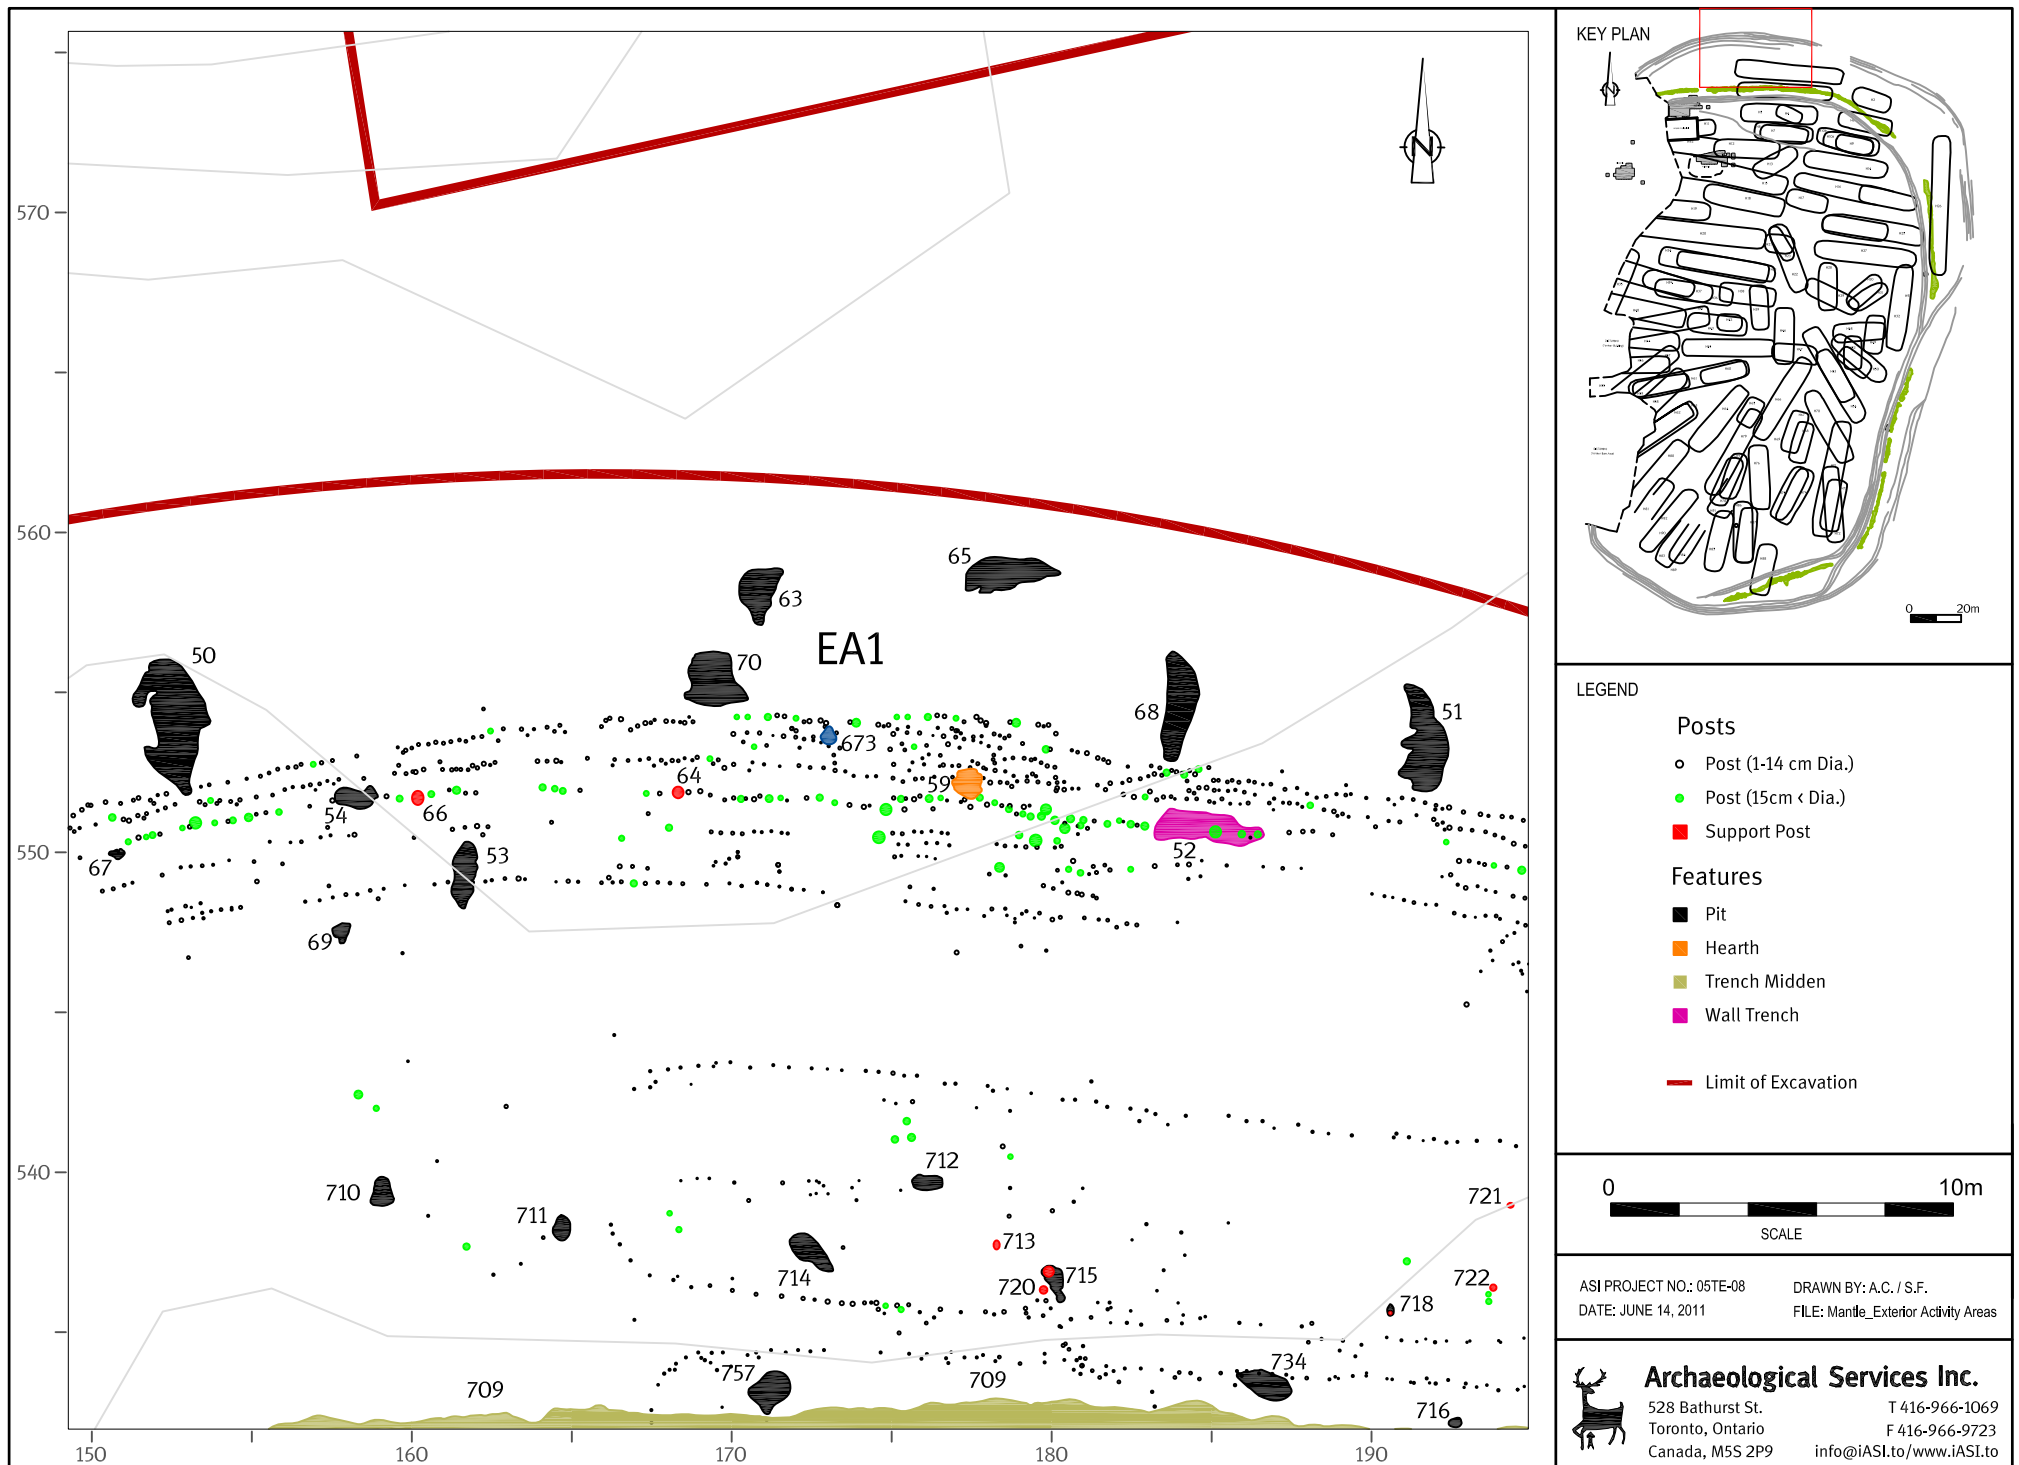

Figure 47: Exterior Activity Area 1

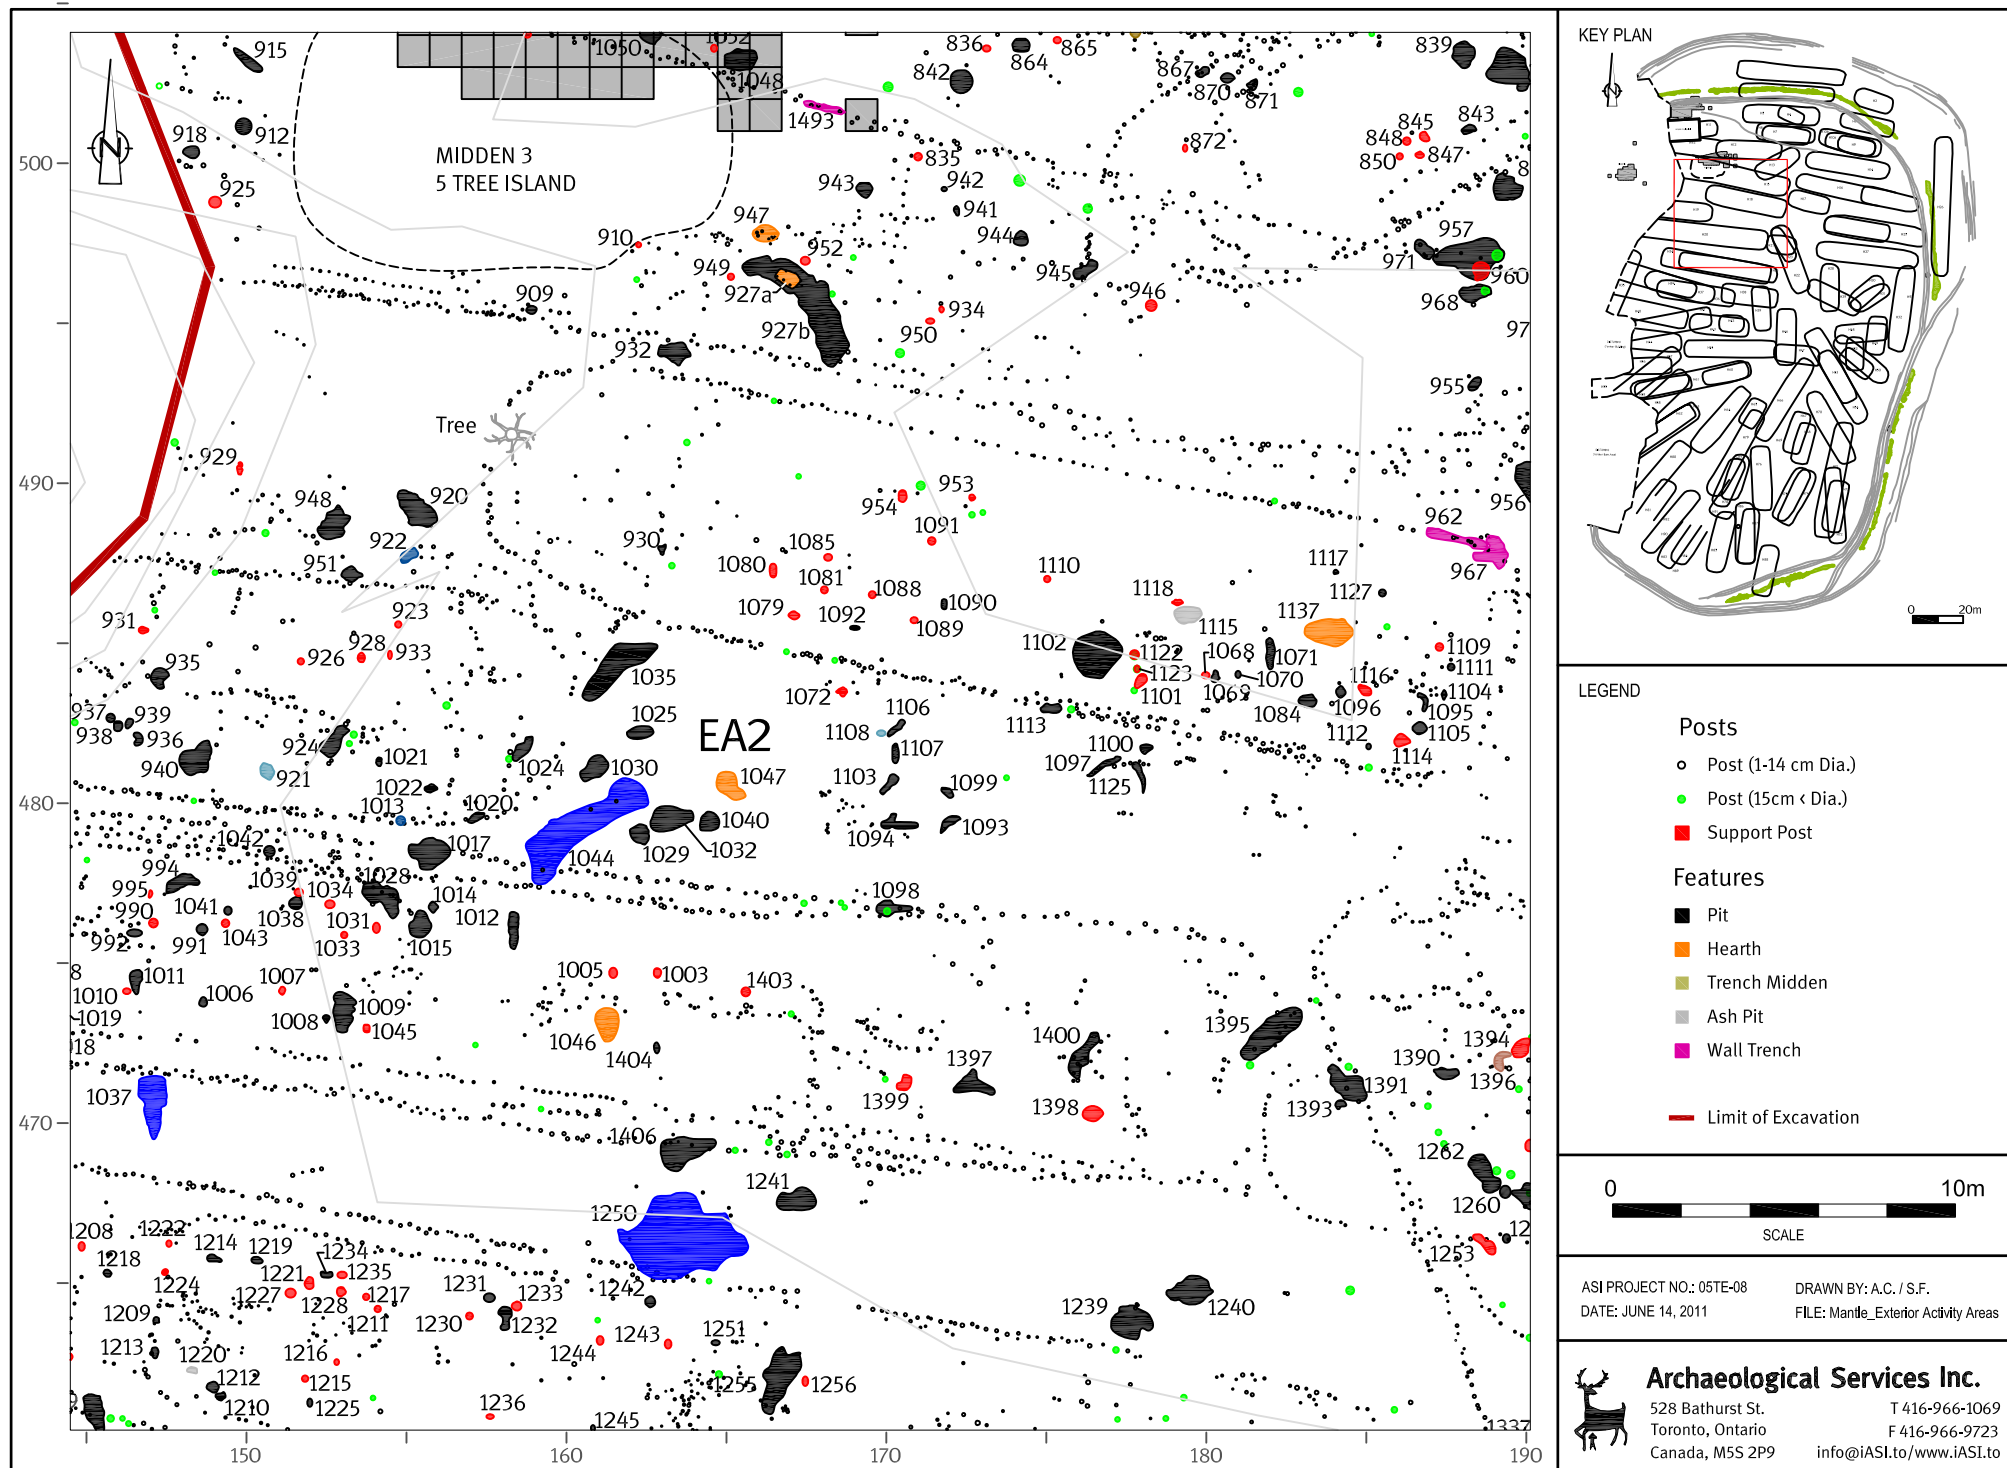

Figure 48: Exterior Activity Area 2

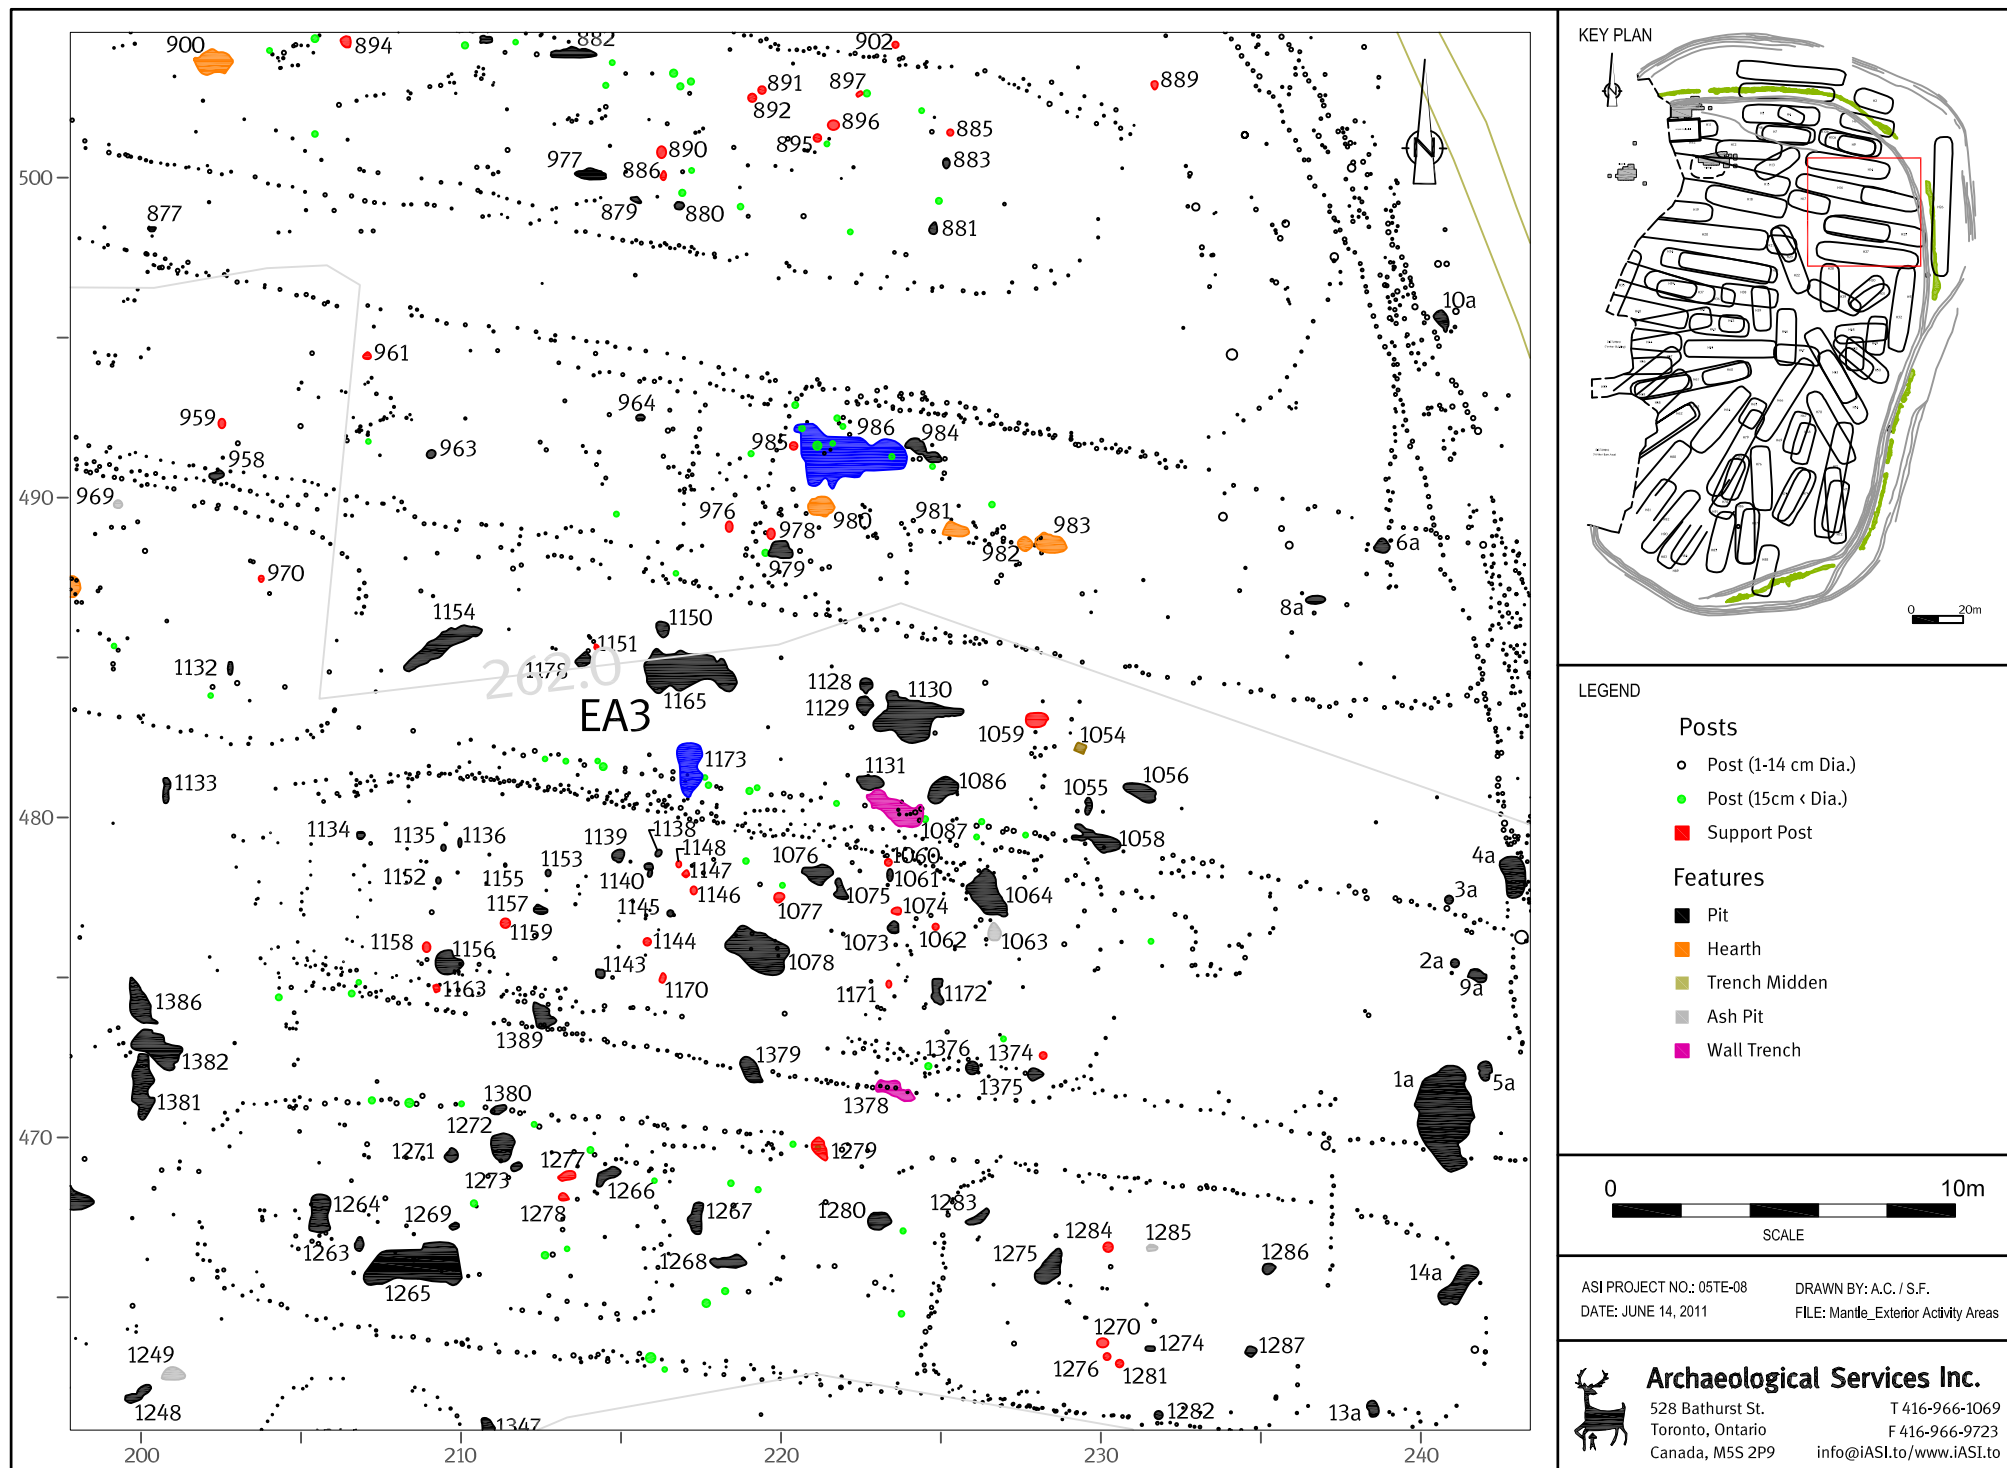

Figure 49: Exterior Activity Area 3

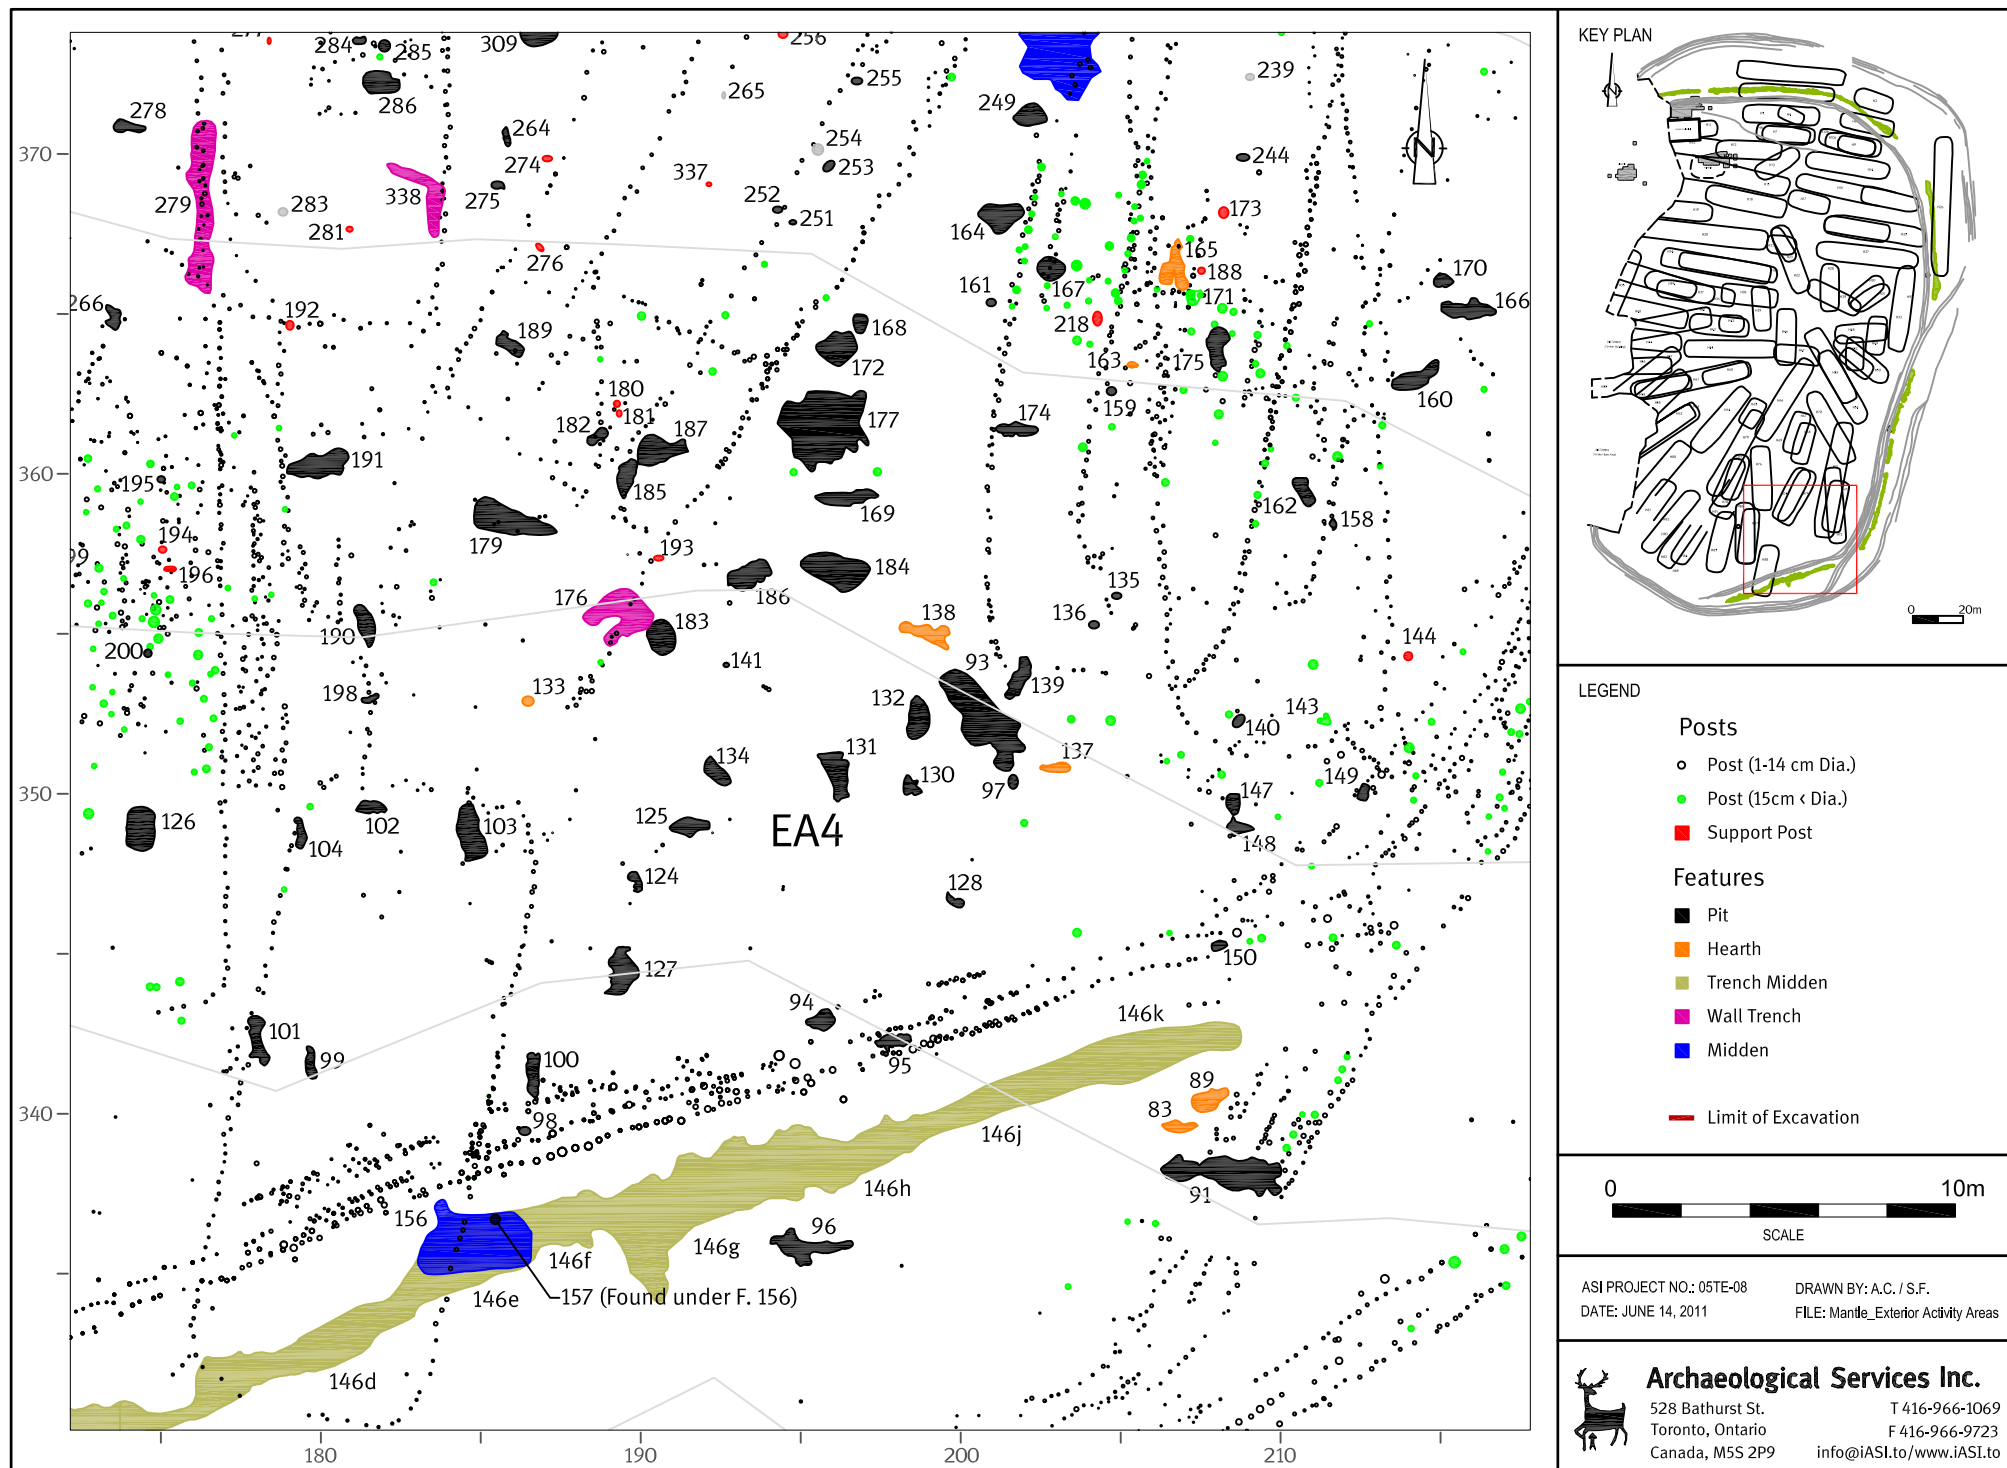

Figure 50: Exterior Activity Area 4

### ***Exterior Activity Area 4***

EAA4 was an irregularly shaped area of roughly 325 m<sup>2</sup> between Houses 88, 74 and 71 (Figure 50). Pit features in this area include (from north to south) Features 168, 172, 177, 169, 179, 184, 186, 183, 141, 93, 139, 132, 131, 130, 134, 125, 124, 128, 127, 100 and 94. Hearth features 133, 137 and 138 are also included in this area (Appendix B). Since there are numerous houses in the immediate area belonging to both the early and late phases of occupation, it is probable that this exterior area was in use throughout the occupation of the site.

## **2.6 Middens**

During the excavation of the Mantle site, three discrete middens were identified in the northwest portion of the site. In the field, they were labelled Middens 1, 2 and 3. As excavation proceeded and excavators came to understand the nature of these deposits and of the disturbance related to the farmhouse that once occupied this area of the site, it became apparent that Middens 2 and 3 were redeposited from Midden 1, most likely during the excavation of the basement of the farmhouse and the movement of soils related to the occupation of the house (for example, from gardening activities). It is now apparent that the only intact midden deposits at the site were the large, hillside Midden 1 and the trench midden that surrounded the third and final palisade phase. The stage three excavations confirmed that there were no additional midden deposits present.

These findings imply that the refuse disposal patterns at the Mantle site were highly organized much more so than might be expected for a site of this size. For example, the Draper village had 22 discrete midden deposits within the village precinct. In the Mantle village, specific energies were directed at managing refuse disposal practices, channeling waste out of the village and into, first, Midden 1 (and any other now-destroyed hillside middens), and later, the trench surrounding the palisade. The social and political implications of these decision-making processes are discussed in greater detail by Birch (2010: 136-137 and Birch and Williamson 2013).

Therefore, only Midden 1 and the Trench Midden are described below.

### ***Midden 1***

Midden 1 is situated on the slope leading to Stouffville Creek. The full extent of Midden 1 was difficult to estimate, as large sections were impacted by historic period building activities. Midden 1 was approximately 15 meters in diameter east to west, and was only partially excavated following a decision to abandon its excavation since it was situated beyond the top of slope line, which was staked only after excavations had proceeded.

The nineteenth-century mill and farmhouse seem to have obscured the eastern and northern limits of the midden, and the southern limit was impacted by a gully that led down to the associated mill race. There may have been other hillside middens impacted by these disturbances, though they too would have been located on the west side of the village above the creek. Thirty-seven one-metre units were excavated in Midden 1, the depths of which ranged between 30 and 120 cm. The yields are all listed in the artifact catalogues.

### ***Trench Midden***

The third phase of palisade construction involved the excavation of a trench around the outside of it. This trench was probably created in order to build an embankment around the base of the palisade to strengthen it. The trench midden extends across the northern, eastern and half of the southern boundaries of the site (Figure 5).

Profiles of the palisade trench feature indicate that it extended to a depth of 15 to 25 cm below subsoil. Given the removal of overlying plough-disturbed soils, this indicates that the original trench may have been originally been 50 cm deep, and should therefore not be considered to have been a defensive structure. Subsequently, this trench feature was filled in with refuse, creating a “trench midden.” The palisade trench may have offered a convenient alternative to the large hillside midden later in the occupation of the site.

The trench was excavated in sections, and these will be described here in clockwise order, beginning in the northern segment of the site. The portion extending across the northern segment of the site was designated Feature 709 (Plates 8-9 and Appendix B). This feature was disturbed both by a cable trench and by the roadway that used to lead to the farmhouse. South of this disturbance, the trench was relabeled Feature 55, though it is probable that this feature continued unbroken around this portion of the site in pre-contact times. In the area in which the three palisade phases meet (between the PE3 and PE 4 described above), there is a 30 metre long break in the trench midden. It then resumes as Feature 85. This section was excavated in blocks (85a-85q). Another short (12 metre) break in the trench corresponds with the area in which the second and third palisade phases meet, which suggests that the trench was excavated while the Phase 2 palisade, or portions thereof, was still standing. Along the southeast portion of the site, this trench resumes as Feature 146, which was also excavated in blocks (146a-146k) (Appendix B).

Plate 8: Trench Midden, Feature 709 Plan View

Plate 9: Trench Midden,  
Feature 709 Profile View

### ***Refuse-filled Depressions***

A number of other refuse-filled depressions were identified within the village itself (from north to south, Features 986, 1173, 1044, 1037, 1250, 1324, 427, 429, 569, 568, 475, 346, 238, 105, 156) (Appendix B). These were originally classed as midden features, but their relatively shallow depths suggest that they were instead simply refuse-filled depressions related to exterior activities at the site. The largest of these (Features 427 and 429; Figures 25 and 46) were located in the plaza area (Plates 10-11).

Plate 10: Feature 427 Plan and Profile View

Plate 11: Feature 429 Profile View

## 2.7 Population Estimates

Constructing population estimates based on settlement patterns can be challenging. Fundamental problems arise when attempting to calculate the population of sites that had dynamic histories of occupation. Warrick thoroughly reviewed the strengths and weaknesses of a variety of approaches, and concluded that settlement remains should highly positively correlate with momentary population (2008:52-72).

This report uses a formula based on research by Casselberry (1974) to estimate population. Based on ethnographic descriptions of eight tribal societies in which residence in multi-family dwellings was the norm, as was the case for precontact Iroquoian society, Casselberry suggested that “the population of a multifamily dwelling can be roughly estimated as one-sixth the floor area of the dwelling as measured in square metres” (1974:119). Casselberry acknowledges that

*...this formula correlates better with the data presented here than do... other formulae, [but] it is still far from a good predictor of population size. The primary reason for this is the large amount of flexibility in human population densities due in part to the various human proxemic systems. (Casselberry 1974:119)*

Ethnographic descriptions of life in Huron-Wendat longhouses suggest that these structures were crowded and “filled with fire, smoke, naked bodies and dogs” (Tooker 1964:40). As such, we might assume that the proxemic systems of the Huron-Wendat, and perhaps their ancestors, were amenable to more densely populated dwellings than in some other societies. It may therefore be prudent to take the figures calculated using Casselberry’s formula as a low estimate of population density.

### 2.7.1 Calculating the Population of the Mantle Village

Due to the dynamic nature of occupational history of the Mantle village, generating an accurate estimate of the number of people who inhabited the site is difficult. In order to estimate the momentary population

of the site using Casselberry's formula, a site plan was generated that most precisely represents current understanding of village layout (Figure 51).

The third palisade phase defined the limits of the site in this representative model because the wall post and feature densities of the northernmost houses in the village, between the first, second and third palisade phases, were not occupied for as long as houses in the rest of the village. Furthermore, the average wall post density of houses associated with the early phase of occupation was 3.6 posts per metre, compared to an average of 4.2 posts per metre in the late phase, suggesting the settlement plan represented by the late village reconstruction (Figure 7) was in place longer than that of the early village.

The next step was to remove houses that were placed in the late phase, but that overlapped with other structures and therefore could not have existed contemporaneously. In the cases of houses that shared a similar footprint, it is possible that these structures housed the same people, which meant that one house could be easily eliminated without affecting the integrity of the estimate (for example, Houses 74 and 75). In cases in which the length of structures was extended (for example, Houses 53 and 54, and House 64) or merged (for example, Houses 70a, 70b and 70c) the maximum house length was retained. Figure 51 illustrates the resulting village plan used to calculate this momentary population.

### **2.7.2 Estimated Population**

Based on the above formula and methods, the estimated total representative, momentary population of the Mantle village was 1339 persons (see also Birch and Williamson 2013).

## **2.8 Settlement Patterns: Discussion and Summary**

Analyses of the occupational history of the Mantle site revealed a number of important insights about this community and how it changed over time. Early, late and intermediate phases of occupation were identified that relate to three phases of palisade construction and the construction and occupation of 98 individual structures.

The earliest structures in the village appear to have been Houses 13 and 26. These structures may have provided shelter for the initial group of builders sent to prepare the site for habitation.

Fifty-four houses were assigned to the early phase of occupation, which was contemporary with the first and second phases of palisade construction (Figure 6). Early-to-middle and early-to-late phase houses were also included in this group. During this phase, houses were predominantly arranged in parallel rows in the northern part of the village, and in a radial alignment on the west and south side's perpendicular to the slope. The central portion of the site adjacent to the eastern palisade was left open to serve as a central plaza. At times, temporary structures were erected in this plaza area.

Fifty houses were assigned to the late phase of occupation, which was contemporary with the third phase of palisade construction (Figure 7). This also included some early-to-late and mid-to late phase houses. The village plan from this late phase was somewhat less rigid than in the early phase, with houses constructed to fit into the remaining available space, including an infilling of the plaza with new structures.

ASI PROJECT NO.: 05TE-08 DRAWN BY: J.B.  
 DATE: JUNE 28, 2011 FILE: 05TE-08\_Mantle\_Momentary\_Population

Figure 51: Momentary Population Estimate of the Mantle Site (AlGt-334)

Calculations of house wall post density (Table 1) suggest that the early phase of the village plan did not persist as long as the late phase. Structures in the northernmost portion of the village (Houses 1, 2, 3, 6) were not occupied for a very long time, or at least not long enough for them to require rebuilding that would have raised the density of wall posts over 3.5 posts per metre. Average wall post density of all early phase houses was 3.6 posts per metre, while late phase houses had 4.2 posts per metre. This also supports the assertion that the late phase of occupation lasted longer than the early phase, and suggests that the highly organized village plan, as initially envisioned, did not persist over time.

Defense seems to have been an important concern for the Mantle community, as evidenced by the construction and maintenance of the multi-row palisade surrounding the village. In its final formulation, this palisade was contracted and structurally modified to include a borrow trench and probably a strengthening embankment. The reasons for the contraction are unknown.

Finally, the residents of the Mantle community employed a waste management strategy whereby refuse was channeled first into a single large hillside midden and later into the borrow trench. This implies a significant degree of organized communal decision-making and/or leadership (see Birch 2010; Birch and Williamson 2013).

### 3.0 CERAMIC ARTIFACT ANALYSIS

*Robert B. Wojtowicz and Aleksandra Pradzynski*

A total of 96,405 ceramic artifacts (Table 2) was recovered from the excavation at Mantle. Ninety-four thousand five hundred and sixty-six fragments are portions of vessel rims, necks, shoulders, and bodies individually or in various combinations. An additional 550 fragments are identified as miscellaneous fired clay or ceramic objects. Five hundred and forty-eight smoking pipe fragments and 749 juvenile manufactured ceramic vessel and pipe fragments were also recovered and are discussed in detail in Sections 3.1 and 3.2 below. Catalogues of the ceramic assemblage and supplementary data are provided in Appendices B through G.

Whenever possible, all ceramic artifacts were mended prior to analysis to the minimum number by provenience.

**Table 2: Ceramic Artifacts from the Mantle site (AlGt-334)**

Type	n	%
Unanalyzable Fragments	60536	62.79
Body Fragments	22571	23.41
Neck Fragments	3956	4.10
Unanalyzable Rim Fragments	3176	3.29
Neck-Shoulder Fragments	2038	2.11
Identified Vessels	1992	2.07
Juvenile Ceramics	741	0.77
Pipe Fragments	548	0.57
Misc. Fired Clay	499	0.52
Shoulder Fragments	210	0.22
Neck-Shoulder-Body Fragments	71	0.07
Misc. Ceramic Artifacts	51	0.05
Shoulder-Body Fragments	16	0.02
Total	96405	99.99

#### 3.1 Ceramic Vessels and Miscellaneous Ceramic Objects

The ceramic vessel assemblage consists of 1992 identified vessels, 3176 unanalyzable rim fragments, 3956 neck fragments, 2038 neck and shoulder fragments, 71 neck-shoulder and body fragments, 210 shoulder fragments, 16 shoulder-body fragment and 22571 body fragments. Ceramic fragments that were smaller than 23 mm or displayed excessive exterior exfoliation were classified as unanalyzable. These account for 60536 fragments, or 62.79% of the total ceramic assemblage (Table 2).

Of the 22658 body fragments identified, 2,577 (11.37%) display evidence of decoration or surface treatment other than plain. The identified surface treatments consist of smoothed over cord (n=1,050; 40.74%), smoothed over ribbed paddle (n=957; 37.13%), smoothed over check stamp (n=91; 3.53%), scarified (n=1; 0.03%) or are classified as indeterminate (n=9; 0.35%). An additional 467 body fragments exhibit decorative motifs generally associated with a shoulder (see section 3.6 below for detailed descriptions).

### 3.1.1 Vessel Rims

Rims were considered analyzable if they exhibited interior and exterior surfaces, a lip, and sufficient exterior collar-neck area to ascertain decorative motif and associated attributes. The vessel rims were analyzed using both attribute-based and traditional typological approaches. All rims were sorted and mended into 1992 individual vessels, of which 78 are represented only by castellation fragments and are not included in the following discussion.

Summary descriptions of individual attributes are presented in Tables 3, 4, 5 and 6.

**Table 3: Ceramic Vessel Descriptive Attributes**

Rim Form	n	%	Collar Base Shape	n	%	Rim Orientation	n	%
Collared	1616	84.43	Rounded	1515	79.15	Outflaring	1878	98.12

Total	1914	100.00	Straight over Convex	1	0.05
			Concave over Straight	1	0.05
			Total	1914	100.00

Collar Height (n=1740)				
Mean				17.22
Range				4.81-86
Standard Deviation				17.22

Lip Width (n=1914)				
Mean				6.57
Range				1.18-14.29
Standard Deviation				1.93

Basel Collar Width (n=1740)				
Mean				9.2
Range				2.6-18.15
Standard Deviation				2.01

Developed collar forms dominate (84.43 %) the assemblage. In contrast, incipient forms constitute a mere 6.43% of the identified vessels. The one hundred and seventy-five remaining vessels are collarless.

Collar base shape of the rounded type is identified on 79.15 % of the vessels, whereas 11.76% of the vessels have angular collar base shapes. The remaining vessels are collarless.

A majority of vessels display a rounded lip form (62.96 %), while the remainder of the vessels display lip forms that are flat (n=531), concave (n=164), rounded and moulded (n=7), irregular (n=3), chamfer (n=2),

pointed (n=1) and indeterminate (n=1). The angles of the lip to the interior are 90 degrees or right (45.04%), obtuse (31.61%), or acute (23.25%). Two vessels display indeterminate lip angle. Rim orientation varies from out-flaring (98.12%) to vertical (0.99%) to in-sloping (0.89 %).

The proportions of convex, concave and straight interior collar profiles are 80.62%, 11.76% and 7.52%, respectively. An additional two vessels display an interior profile that are classified as convex over convex and indeterminate, respectively.

The exterior profiles of the vessel collars are concave (56.37%), convex (36.94%) and straight (4.39%). An additional 44 vessels display complex exterior profiles that consist of two or more of the above-mentioned attributes or are of indeterminate type.

Collar heights in this assemblage range between 4.81 mm and 86 mm, with a mean height of 17.22 mm and a standard deviation of 8.07. Lip widths range between 1.18 mm and 14.29 mm, averaging 6.57 mm with a standard deviation of 1.93. Basal collar widths range between 2.6 mm and 18.15 mm, with a mean of 9.2 mm and a standard deviation of 2.01.

The interiors of the vessels are principally plain (90.65%). An additional 170 vessels (8.89%) have decoration dominated by a single band of oblique or vertical lines. The remaining nine vessels (0.46%) exhibit one of four different motifs and techniques.

**Table 4: Interior Descriptive Attributes**

<b>Interior Motif</b>	<b>n</b>	<b>%</b>	<b>Interior Technique</b>	<b>n</b>	<b>%</b>

<b>Total</b>	<b>1914</b>	<b>100.00</b>	Linear Stamp over Punctate	1	0.05
			<b>Total</b>	<b>1914</b>	<b>100.00</b>

Lip motifs are identified on 703 vessels and are distributed in the following positions: lip (n=361); frontal lip (n=241); lip and frontal lip (n=70); rear lip (n=23); and rear lip and frontal lip (n=7). One vessel displays a motif on the rear lip, lip and frontal lip. Linear stamping, notching, punctates, cording, incising, and push-pulling are all techniques used in the manufacture of the motifs identified on vessels lips. Additionally, frontal lip notching or frontal lip motif is identified on 16.61% of the vessels at Mantle.

One hundred and nineteen different collar motifs (on collared or incipient collared vessels) are identified within the assemblage (Table 6), and are distributed as follows: simples (58.83%); opposed (10.71%); plain collared (7.89%); crossed (2.56%); interrupted (2.40%); horizontals (1.72%); hatched (0.57%); and collarless (9.14%). The remaining specimens are either classified as complex, or exhibit a motif that is shared by two or more of the traits identified by Ramsden (1977). The most common techniques utilized in the manufacture of the collar motifs are: linear stamping (43.94%); incising (20.90%); plain (7.05%); and linear stamping crossed by incising (2.66%). The remaining 312 vessels exhibit 85 different techniques.

Basal collar notching or a motif is identified on 4.64% of the vessels from the Mantle Site.

Neck motifs (including collarless vessels) are predominantly plain (89.55%), but are also occasionally oblique (3.71%), horizontal (1.88%), or oblique over unknown motif (1.36%). The remaining 67 vessels (3.50%) utilize one of 29 different motifs (Table 7). Aside from plain, the techniques of punctates (3.08%) and linear stamping (2.04%) are the most common identified methods of motif manufacture on the necks. The remaining 102 vessels (5.33%) display 29 different techniques.

### 3.1.2 MacNeish Types found on Ontario sites

Table 8 provides an overview of specific ceramic vessel types based largely on MacNeish (1952). In his study of Iroquoian pottery types, MacNeish describes a type as “a class or group of objects having interrelated similar features or modes that have a temporal or spatial significance” (1952:2). Thus, this approach uses the attributes of neck and collar motif, and rim shape, to construct classificatory types based upon the assumption that sets of combined attributes (types) represent a style in the mind of the potter. These were thought, in turn, to reflect trends in time and space in which similarities and differences in frequencies of types between assemblages might relate to ethnic identity and chronological placement (Wright 1966:17). Subsequent critics of typological studies (e.g., Ramsden 1977: 16-18; Smith 1983: 10-14) have questioned the simplistic methodology and inadequate sample used in the original definitions of types. Indeed, many Ontario researchers have recognized the advantages of attribute analysis in providing for more detailed and comparative descriptions of assemblages. Nevertheless, it remains useful to report on the frequencies of types in assemblages for comparative purposes if one provides an accurate account of each type. To this end, key attributes and variability for each type are described in detail below. For this analysis, collared, incipient collared and collarless vessels have all been used.

**Table 8: Ceramic Vessel Types**

**Huron Incised**

One thousand and seventy-one vessels representing 55.96% of the total vessel assemblage are Huron Incised. These vessels exhibit interior collar profiles that are either convex (n=984) or straight (n=87). Interior decoration is identified on 13.63% of the vessels of this type, and is dominated (95.89%) by a single band of obliques or vertical lines.

Lip decoration is present on 14.95% of these vessels. The most common motif (81.88%) is a single band of oblique or vertical lines that may or may not be interrupted. This is followed by a single horizontal line manufactured by a variety of techniques (5.63%), rear lip notching (n=9), cording (n=4) or a simple band of oblique or vertical lines over or crossed by a horizontal line (n=3) (Table 9).

**Table 9: Huron Incised Lip Motifs**

<b>Total</b>	<b>1071</b>	<b>99.97</b>

When rim form, collar and neck motifs are examined, it is clear that most Huron Incised vessels at Mantle display a single band of oblique or vertical lines on a developed collar with a plain neck. These account for 73.20% of the type assemblage (Table 10). The remaining 287 vessels utilize 62 different combinations of rim form, collar and neck motif. Plates 12 to 15 illustrate Huron Incised vessels.

### ***Sidey Notched***

One hundred and eighty two vessels were classed as Sidey Notched. These represent 9.56% of the total vessel assemblage.

Sidey Notched vessels exhibit either convex (n=170) or straight (n=12) interior collar profiles. Interior motifs are identified on 3.3% of the vessels and consist of a single band of oblique, vertical or horizontal lines manufactured by either linear stamping or punctates. Table 11 displays the variability in Sidey Notched lip motif.

**Table 11: Variability in Sidey Notched Lip Motif**

<b>Lip Motif</b>	<b>n</b>	<b>%</b>

Notched over Notched (FL)	2	1.1
Horizontal	1	0.55
<b>Total</b>	<b>182</b>	<b>100.01</b>

When rim form, collar and neck motifs are examined, 72.53% of all Sidey Notched vessels have a single band of oblique or vertical lines on a developed collar with a plain neck (Table 12). The remaining 50 vessels utilize 29 different combinations of rim form, collar and neck motif. Plates 16 to 18 illustrate Sidey Notched vessels from Mantle.

**Lawson Incised**

One hundred and forty-four vessels are Lawson Incised and all display concave interior profiles. Interior decorative motifs are identified on three vessels and consist of a simple band of oblique or vertical lines manufactured by linear stamping. The remainders are plain.

Lip motifs are identified on 45.83% of the vessels, of which 29.17% exhibit a simple band of oblique or vertical lines. The remaining 24 vessels exhibit nine different lip motifs, including examples of notching on the lip and frontal lip (Table 13).

**Table 13: Variability in Lawson Incised Lip Motif**

<b>Total</b>	<b>144</b>	<b>99.97</b>

Many Lawson Incised vessels have a simple band of oblique or verticals lines on a developed collar with a plain neck (27.78%). The remaining 104 vessels display 35 different motifs. Table 14 displays the different combinations of collar and neck motifs with associated rim forms. Lawson Incised vessels from Mantle are illustrated in Plate 19.

Plate 19: Lawson Incised (Cat. #CS45 and Cat. #CS71)

**Dutch Hollow Notched**

One hundred and twenty one vessels (6.32% of the total vessel assemblage) are Dutch Hollow Notched often identified as originating with the Seneca. Variations in rim form and interior profile are illustrated in Table 15. Fourteen vessels are identified as having a collared or incipient rim form, but these are actually more reminiscent of a folded over lip than a true collar.

**Table 15: Variability in Dutch Hollow Notched Rim Shape**

<b>Rim Form</b>	<b>Interior Profile</b>	<b>n</b>	<b>%</b>
Collarless	Convex	93	76.86
Collared	Convex	10	8.26
Collarless	Straight	8	6.61

Collared	Concave	2	1.65
Incipient	Convex	1	0.83
Collared	Straight	1	0.83
<b>Total</b>		<b>121</b>	<b>100.00</b>

Interior motifs are identified on five vessels of this type and consist of a simple band of oblique or vertical lines manufactured by linear stamping.

The most common lip motif encountered is frontal lip notching, which appears on a total of 85.12% of the vessels individually or in conjunction with other lip or rear lip motifs (Table 16).

**Table 16: Variability in Dutch Hollow Notched Lip Motif**

### ***Seed Incised***

Seed Incised vessels display either a convex (81.82%), concave (10.23%) or straight (7.95%) interior profile on either a developed (90.91%) or incipient collar (9.09%). Interior motifs are identified on six vessels as a simple band of oblique or vertical lines manufactured by linear stamping. The remainders are plain. Lip motifs are found on the majority of the vessels (Table 18).

### ***Niagara Collared***

These vessels exhibit convex (66.27%), concave (16.87%), straight (15.66) and convex over convex (n=1) interior profiles on developed (79.52%) or incipient collars (20.48%).

Lip motifs are identified on 14 vessels (16.87 % of the total type assemblage), and motifs consist of a simple band of linear stamped oblique or vertical lines (n=9), notching (n=4) or simple band of incised oblique lines (n=1).

All vessels of this type display a plain interior. Table 20 displays collar and neck motifs with associated rim forms. Plate 24 provides illustrations of Niagara Collared vessels.

**Table 20: Variability in Niagara Collared Rim Form, Collar and Neck Motif**

Rim Form	Collar Motif	Neck Motif	n	%

### ***Black Necked***

Black Necked vessels comprise 2.04% of the total vessel assemblage. These vessels display convex (n=31), straight (n=5) and concave (n=3) interior profiles on either a developed (94.87%) or incipient collar (5.13%).

Lip motifs are identified on eight of the vessels as a simple band of linear stamped vertical or oblique lines (n=4), notching (n=2) or frontal lip notching (n=2). One vessel exhibits an interior motif consisting of a simple band of linear stamp oblique lines. The remaining vessels are plain.

Table 21 displays 25 different combinations of collar and neck motifs with associated rim forms. Black Necked vessels are illustrated in Plate 25.

**Warminster Horizontal**

Twenty vessels are classified as Warminster Horizontal, and these vessels display either a convex or straight interior profile on a developed collar. Five vessels display five different lip motifs, while two vessels display a simple band of linear stamped oblique lines on the interior.

Table 22 displays nine different combinations of collar and neck motifs with associated rim forms. Vessel examples are presented in Plates 26 and 27.

**Table 22: Variability in Warminster Horizontal Rim Form, Collar and Neck Motif**

Plate 27: Warminster Horizontal (Cat. #10527)

**Seed Corded**

These vessels display collared rim forms with convex (n=13) or straight (n=2) interior profiles and plain interiors. Lip motifs are identified on 80% of the vessels of this type and consist of cording (n=2), cording and frontal lip notching (n=6), frontal lip notching (n=3), or a simple band of linear stamped oblique lines (n=1).

Table 23 displays nine different combinations of collar and neck motifs with associated rim forms. Two Seed Corded vessels are illustrated in Plate 28.

**Table 23: Variability in Seed Corded Rim Form, Collar and Neck Motif**

<b>Total</b>			15	100.01

Plate 28: Seed Corded (Cat. #10323 and Cat. #10430)

### ***Rice Diagonal***

The twelve vessels identified as Rice Diagonal display either a collarless (n=11) or a collared profile with a convex interior.

Interior motifs are identified on two vessels as a single band of linear stamped or linear punctate oblique lines. A lip motif is identified on all the vessels, of which eleven display a simple band of oblique or vertical lines over frontal lip notching. The twelfth vessel displays a simple band of oblique lines on the lip, with notching on the collar. This vessels rim form is more reminiscent of a folded over lip than a true collar, similar to some Dutch Hollow Notched vessels.

Table 24 displays nine different combinations of collar and neck motifs with associated rim forms. Plate 29 displays an example a Rice Diagonal vessel.

**Table 24: Variability in Rice Diagonal Rim Form, Collar and Neck Motif**

<b>Rim Form</b>	<b>Collar Motif</b>	<b>Neck Motif</b>	<b>n</b>	<b>%</b>
Collarless	Collarless	Plain	10	83.33
Collared	Notched	Plain	1	8.33
Collarless	Collarless	Vertical	1	8.33
<b>Total</b>			<b>12</b>	<b>99.99</b>

Plate 29: Rice Diagonal (Cat. #10310)

### ***Ontario Horizontal***

The eleven Ontario Horizontal vessels display a great deal of variation in rim shape and motif. Variations include a concave (n=9) or convex (n=2) interior profile on a collarless (n=1), incipient (n=6) and collared rim form (n=4) with a plain interior.

Lip motifs are identified on seven of the vessels and consist of a simple band of linear stamped oblique lines (n=2), frontal lip notching (n=3) and rear lip notching (n=2). Table 25 displays 10 different combinations of collar and neck motifs with associated rim forms.

**Table 25: Variability in Ontario Horizontal Rim Form, Collar and Neck Motif**

Rim Form	Collar Motif	Neck Motif	n	%
Incipient	Horizontal	Horizontal	2	18.18

Incipient	Oblique over Horizontal over Vertical	Plain	1	9.09
Total			11	100.00

***High Collar***

The single High Collar vessel displays a convex interior on a developed collar measuring 84.51 mm in height. The collar motif consists of three alternating bands of oblique and horizontal lines manufactured by both incising and linear stamping. These are placed over a band of basal collar notching (Plate 30).

Plate 30: High Collar (Cat. #9233)

***Ripley Plain***

These vessels all display collarless rim forms with convex (n=21), concave (n=3) and straight (n=1) interior profiles. One vessel displays an interior motif consisting of a simple band of oblique incised lines.

Lip motifs are found on more the half of the vessels, and can be identified by: notching on the lip (n=5); a simple band of oblique lines on the lip or frontal lip motif manufactured by linear stamping (n=6); incising (n=1); or a single horizontal row of punctates. The exteriors are plain.

### ***Neutral Punctate Lip***

The three Neutral Punctate Lip vessels display a convex interior on either an incipient (n=2) or collarless rim form with a convex interior. All the vessels display a single horizontal band of punctates on the lip, with a plain interior and exterior.

### ***Ontario Oblique***

Two vessels are classified as Ontario Oblique. The first vessel displays a convex interior on a collarless rim form, and has an exterior motif consisting of two bands of linear stamped oblique lines. The second vessel displays a convex interior on an incipient collar decorated by a simple band of linear stamped vertical lines. The neck exhibits a plain motif over a simple band of linear stamped vertical lines. Both vessels display a simple band of oblique lines on the lip and a plain interior.

### ***Pound Blank***

The first vessel of this type displays a convex interior on a collared rim form decorated by interrupted oblique band of punctates over a single horizontal band of punctates. The other vessel of this type has a convex interior on an incipient collar, which is decorated by a simple band of punctates over an opposed pattern made up of incised left and right oblique lines and plain isosceles triangles. Both vessels display a plain neck, lip and interior.

### ***Ripley Corded***

The lone Ripley Corded vessel displays a convex interior on a developed collar. The neck is corded, while the lip, interior and collar are plain.

### ***Lalonde High Collared (LHC)***

The single vessel of this type has a convex interior on a developed collar measuring 42.32 mm in height. The collar is decorated by a single band of punctates at an oblique angle over a thick band of incised oblique lines crossed by a series of incised oblique lines over a single horizontal line. The neck lip and interior are plain.

### ***Middleport Oblique***

The one vessel of this type exhibits a motif of a simple band of incised vertical lines over incised horizontal lines on an incipient collar with plain neck. The interior profile is straight and has a plain lip and interior.

### ***Pound Necked***

This vessel displays a concave interior on an incipient collar decorated by a simple band of incised oblique lines over incised horizontal lines over unknown motif on the neck. The lip and interior are plain.

### ***Indeterminate Type***

Thirty vessels exhibit motifs and shapes that did not correspond to any particular type. The vessels under this classification displayed a wide variety of attributes. Interior profiles identified with these vessels

consist of convex (n=18), concave (n=9), straight (n=2) and irregular (n=1) shapes. One vessel exhibits an interior motif consisting of a single horizontal band of punctates. Table 26 displays the variance in lip motif in these vessels.

**Table 26: Variability in Indeterminate Type Lip Motif**

### 3.1.3 Eastern Types

The eastern types include all those that are more commonly associated with Iroquoian speaking groups along the St. Lawrence River and in central New York State.

#### *Cayadutta-Otstungo and Chance Incised*

Twenty-nine vessels are classified as either Cayadutta-Otstungo Incised or Chance Incised. These two types are distinguished by the presence or absence of either a basal collar notching or motif.

The vessels identified as Cayadutta-Otstungo Incised display concave (72.22%), convex (22.22%) or straight (5.56%) interior profiles. For ease of comparison with New York samples, in this section frontal lip motifs are assumed to be associated with the collar.

Two vessels display interior decoration, which consists of either a horizontal band of punctates or a simple band of linear stamped oblique lines. The rest are plain.

Twelve of the vessels have a simple band of linear stamped vertical or oblique lines on the lip. Two other vessels display a corded-like motif and the rest are plain.

Table 28 displays variation in interior profile shape, lip motif and collar motif. Plain necks are associated with all vessels of this type. Human effigies are associated with the castellation of a number of vessels of this type and are discussed in greater detail in Section 3.1.7. Plates 31-33 provide examples of Cayadutta-Otstungo Incised vessels.

**Table 28: Variability in Cayadutta-Otstungo Incised Interior Profile, Lip and Collar Motif**

Interior Profile	Lip Motif	Collar Motif	n	%
Convex	Plain	Vertical over Horizontal over Opposed (Oblique and Vertical) over Notching (BC)	3	16.67

Plate 33: Cayadutta-Otstungo Incised  
(Cat. #10446)

The vessels identified as Chance Incised display concave (45.45%), convex (45.45%) or straight (9.09%) interior profiles. Interior motifs are associated with two vessels of this type and are identified as a simple band of linear stamped oblique lines. The rest are plain. Four of the vessels have a simple band of linear stamped vertical or oblique lines on the lip. Three vessels have a corded-like motif and the rest are plain.

Table 29 shows variation in interior profile shape, lip motif and collar motif. All vessels of this type have plain necks. Three vessels have a castellation with a human effigy; these are discussed in detail in Section 3.1.4 below.

**Table 29: Variability in Chance Incised Interior Profile, Lip and Collar Motif**

**Roebuck Corn Eared**

The 16 vessels of this type display convex (n=14) or concave (n=2) interior profiles on a developed collar with a plain interior. Seven vessels have a rounded molded lip form that accentuates the corn motif. The rest are rounded (n=8) or flat (n=1). Two vessels have lip decoration consisting of a simple band of linear stamped oblique lines.

Table 30 shows the 11 different combinations of collar and neck motifs and associated rim forms. Plates 34 and 35 show examples of Roebuck Corn Eared vessels.

**Table 30: Variability in Roebuck Corn Eared Rim Form, Collar and Neck Motif**

***Cayuga Horizontal***

The nine Cayuga Horizontal vessels display a great deal of variation in rim shape and motif. They have either a concave (n=3) or convex (n=6) interior profile on a collarless (n=2), incipient (n=4) or collared rim form (n=3) with a plain interior.

Lip motifs consist of simple band of linear stamped oblique or vertical lines (n=3) or frontal lip notching (n=1). The rest are plain.

Table 31 shows the nine different combinations of collar and neck motifs with associated rim forms.

**Table 31: Variability in Cayuga Horizontal Rim Form, Collar and Neck Motif**

Rim Form	Collar Motif	Neck Motif	n	%
Collared	Horizontal	Horizontal	1	11.11
Collared	Horizontal	Plain	1	11.11
Collared	Horizontal and Opposed (Left and Right Oblique)	Oblique	1	11.11
Collarless	Collarless	Horizontal	1	11.11

Incipient	Opposed (Oblique and Horizontal) over Oblique (BC)	Plain	1	11.11
<b>Total</b>			<b>9</b>	<b>100.00</b>

### ***Durfee Underlined***

The single Durfee Underlined vessel displays a convex interior on a developed collar. The collar is decorated by a simple band of linear stamped oblique lines between two incised horizontal lines, and this is over basal collar notching with a plain neck. The interior displays a simple band of linear stamped oblique lines, while a band of notching decorates a frontal lip.

### ***Fonda Incised***

The single vessel of this type displays a convex interior on an incipient collar decorated by a series of horizontal lines over an opposed motif consisting of incised oblique and horizontal lines over a basal collar notching (Plate 36). The lip, interior and neck are plain.

Plate 36: Fonda Incised (Cat. #9237)

### ***Hummel Corded***

This vessel has a concave interior on an incipient collar decorated by an opposed corded motif consisting of oblique and horizontal lines. The lip, interior and neck are plain.

### ***Onondaga Triangular***

This vessel has a concave interior on a developed collar, which is decorated by a complex motif consisting of a plain band over an opposed motif (left and right oblique lines) between two incised horizontal lines and over basal collar notching. The lip, interior and neck are plain.

**Otstungo Notched**

The single Otstungo Notched vessel displays a collarless rim form with a convex interior. The lip is decorated by a series of horizontal lines bordered by notching on the rear and frontal lip area. The neck and interior are plain (Plate 37).

Plate 37: Otstungo Notched  
(Cat. #10432)

**Richmond Incised**

This vessel has a convex interior on a developed collar measuring 86 mm in height, which is decorated by an opposed motif consisting of series of incised vertical, left and right oblique lines. The lip and interior are both plain, while the neck is incomplete but is presumed to be plain as well (Plate 38).

Plate 38: Richmond Incised (Cat. #9232)

### **Thurston Horizontal**

This vessel has a convex interior on a developed collar, which is decorated by a series of incised horizontal lines between two bands of oblique lines over basal collar notching. The lip is decorated by a band of linear stamp oblique lines crossed by a single incised horizontal line. The interior is decorated by a single band of linear stamped oblique lines. The neck is plain.

#### **3.1.4 Vessel Castellations**

One hundred and sixty castellations are identified in the Mantle site assemblage. Seventy-eight of them are isolated fragments, while the remaining eighty-two are associated with the vessels discussed above.

Table 32 displays the frequencies of castellation lip form shapes as defined by Emerson (1955). The Rounded lip form is identified on 36.88% of the castellations, while Grooved (13.13%), Turret (13.13%), Pointed (11.88%) and Rounded Multiple (10.00%) forms comprise the rest. Additional Castellation shapes of Notched, Scalloped, Pointed Multiple and Lug Handle are also present, but only make up 15.01% of the total sample.

**Table 32: Castellation Lip Form Shape**

<b>Lip Form Shape</b>	<b>n</b>	<b>%</b>
Rounded	59	36.88
Grooved	21	13.13
Turret	21	13.13
Pointed	19	11.88
Rounded (Multiple)	16	10.00
Notched	14	8.75
Scalloped	6	3.75
Pointed (Multiple)	3	1.88
Lug Handle	1	0.63
<b>Total</b>	<b>160</b>	<b>100.03</b>

Collar base development at the castellation consisted primarily of the collared form (48.13%), but 36.25% were also overhanging or slightly overhanging. Other collar base forms include incipient (n=21), collarless (n=3), and one slightly overhanging collarless form (Otstungo Notched type).

Table 33 displays 102 different combinations of castellation lip form and collar and neck motif. The most common castellation collar and neck motif is an opposed collar motif of left and right oblique lines over a plain neck. This motif is either associated with a Rounded (11.25%), Turret (5%) or Grooved (4.38%) lip form. Apart from these combinations, there are 99 other combinations of castellation lip form, collar and neck motif. Plates 39-43 show examples of some of these combinations.

**Table 33: Castellation Lip Form, Collar and Neck Motif**

<b>Lip Form</b>	<b>Collar Motif</b>	<b>Neck Motif</b>	<b>n</b>	<b>%</b>

### 3.1.5 Neck Fragments

Six thousand and sixty-five neck fragments are identified apart from the vessel assemblage. Only 5.09% of these fragments exhibit decorative motifs, while 10.45% of the identified vessels display decorative motifs.

### 3.1.6 Shoulder Fragments

Table 34 displays all the shoulder fragments that could be analyzed according to type and decorative attributes. Plain rounded shoulders are most likely under-represented due to the difficulty of accurately identifying rounded shoulders from the vessel body.

**Table 34: Shoulder Type and Decoration**

### 3.1.7 Miscellaneous Ceramic Objects

The miscellaneous ceramic objects consist of 499 pieces of manufacturing waste or fired clay and 51 ceramic artifacts. Table 35 displays the frequencies of miscellaneous ceramic artifacts, excluding isolated strap handle fragments and effigies, which will be discussed in detail below.

**Table 35: Miscellaneous Ceramic Artifacts**

Type	n	%
Miscellaneous Fired Clay	499	92.24
Gaming Discs	27	4.99
Miscellaneous Ceramic Objects	6	1.11
Miniature Vessel	5	0.92
Marbles	2	0.37
Beads	1	0.18
Figurines	1	0.18
<b>Total</b>	<b>541</b>	<b>100.00</b>

#### *Miscellaneous Fired Clay*

The fragments identified as manufacturing waste or fired clay display irregular, untreated surfaces that do not have any apparent form or function. One miscellaneous fired clay fragment has an impression of human teeth marks in it, suggesting that it might have been bitten. Another fragment exhibits possible serrations from a cutting tool.

#### *Gaming Discs*

Twenty-seven ceramic gaming discs were recovered from Mantle, and diameters could be recorded for 17 of these. Disc diameters range between 16.16 mm and 39.69 mm with a mean diameter of 27.3 mm and a standard deviation of 7.28. More than half of all the gaming disks were manufactured from body fragments (n=16). Neck (n=1), neck and shoulder (n=1), and rim (n=1) fragments were also used to make gaming discs. Two discs were freely formed from clay, and one gaming disc was partially perforated.

#### *Miscellaneous Ceramic Objects*

Six artifacts are classified as Miscellaneous Ceramic Objects and may have a variety of functions. Miscellaneous ceramic artifact 12375, recovered from Feature 986, could represent a spur fragment associated with a castellation, and is decorated by simple linear stamped vertical lines. Artifact Cat. #12376 from Feature 54 and artifact Cat. #12381 from Unit 522-142 are both plain and have trumpet shaped profiles with generally irregular surfaces. It is possible that these artifacts may have been pedestal feet for vessels.

Artifact 12378 from Unit 525-147 measures 67.28 mm in length with an approximate diameter of 20.52 mm and has a smoothed plain exterior. The artifact has a hole through the middle that has a diameter of 4.27 mm (Plate 44).

Plate 44: Miscellaneous Ceramic Objects (Cat. #12378 and Cat. #12381)

### ***Miniature Vessels***

Five miniature vessels or pinch pots were recovered, and these displayed a fair degree of variability in skill of manufacture. Each of the five vessels is described below.

The plain collarless miniature vessel Cat. #12382 has a rounded lip measuring 4.98 mm in width with an acute angle. The shoulder is plain and rounded. This artifact was recovered from Feature 76.

The collarless miniature vessel Cat. #12385 has a rounded lip measuring 4.82 mm in width with an acute angle decorated by frontal lip notching. The shoulder is plain and rounded. This miniature vessel was recovered from Midden 2, Unit 525-148.

Collared miniature vessel Cat. #12383 has a rounded lip measuring 3.63 mm in width with a right angle and is decorated by a simple band of linear stamped oblique lines. The collar measures 4.86 mm and is decorated by a simple band of linear stamped vertical lines and has a rounded base that measures 4.26 mm in thickness. The neck, rounded shoulder and body are all plain but display construction striations. This miniature was recovered from Feature 1490 (Plate 45).

Another collarless miniature vessel Cat. #12384 has a rounded lip decorated by linear stamped vertical lines on the frontal lip. The lip measures 3.29 mm with a right angle. The shoulder is plain and rounded. This miniature vessel was recovered from Post 10, Unit 415-130 (Plate 45).

Collared miniature vessel Cat. #12386 has a rounded lip measuring 3.71 mm in width with a right angle and is decorated by a simple band of linear stamped oblique lines. The collar has a height of 6.14 mm and is plain. The collar base is rounded and has a thickness of 4.87 mm. The neck and interior are both plain. This miniature was recovered from Midden 2, Unit 521-142 (Plate 45).

Plate 45: Miniature Vessels (Cat. #12383, Cat. #12384 and Cat. #12386)

### ***Figurines***

Miscellaneous ceramic artifact Cat. #3191 could possibly be the rump of an animal effigy. The exterior is blackened and well burnished and was recovered from Unit 522-147.

### ***Marbles***

Two spherical ceramic artifacts were recovered. One specimen (Cat. #11977) from Feature 238 is smoothed, displays drying fissures on the surface, and has a diameter of approximately 24.56 mm. The second specimen (Cat. #11792) from Midden 1, Unit 497-121, is smoothed and well made, but is too fragmentary to measure.

### ***Beads***

One plain, slightly burnished ceramic bead (Cat. #12340) was recovered from Feature 709. It measures 15.26 mm in exterior diameter, 11.54 mm in height, and has a fired hole with a 3.09 mm diameter.

### ***Effigies***

Fifteen three-dimensional human face effigies and effigy fragments were identified in the Mantle site assemblage (Plates 46 and 47). Of the human face effigies, nine are complete or nearly complete, while the remaining six fragments vary in completeness and size. Most of the effigies appear to be associated with the types Cayadutta-Otstungo Incised or Chance Incised, though a few are fragmentary and could be associated with other types.

The mostly complete effigies all appear to have rounded to oval shape and were most likely molded or, in a few examples, attached as appliqués to the collar surface under the castellation. In addition, one vessel (Cat. #11469) of the type Cayadutta-Otstungo Incised exhibits a scar where the effigy was no longer present.

The effigies depict only the eyes nose and mouth, and display a fair amount of variation. The eyes are generally depicted as either a narrow slotted line (n=2), oval punctate or molded surface (n=3) or by either three stamped lines or a narrow slot in a molded or punctated depression (n=7). The noses are typically damaged, and data for only seven effigies are available. Four are well-defined with an incised line for the nostrils, while the three remaining specimens exhibit only short, rounded punctates for the nostrils. The mouth is typically open and has an oval molded or punctated shape (n=6), an open slot (n=2) or two punctates (n=1). Two of the effigies depict a narrow slot for the mouth.

Plate 46: Human Face Effigy (Cat. #CS100)

Plate 47: Human Face Effigy associated with the type Chance Incised (Cat. #CS99)

### ***Handles***

Nineteen ceramic handles, handle fragments or handle scars are identified in the Mantle assemblage. The ceramic handles include one body sherd with partial handle fragment; four shoulders (of which two are scars); and two rim fragments (of which one is partial and one is complete). Four identifiable vessels have strap handles; two are complete and one is fragmentary. Another specimen displays a scar on the collar and shoulder. The remaining eight specimens are isolated handle fragments and are classified as miscellaneous ceramic artifacts.

Thirteen handles are sufficiently complete to obtain a cross-sectional profile. Most display a pentagonal (n=4) or rectangular (n=4) cross section. Oval (n=3), triangular (n=1) and irregular (n=1) shapes is also present.

Decoration was observed on 13 of the 19 fragments, with short linear stamped or incised lines identified on three of the sides on 11 of the handles. In addition, one handle displays two horizontal incised lines that traverse the length of the handle crossing the short stamped lines. The remaining handle is oval and plain.

### **3.1.8 Vessel Recycling and Finger Prints**

Evidence of vessel recycling appears exclusively as mend holes, presumably used for lashing two or more fragments of the same vessel back together to prolong its use-life. Mend holes are identified on 31 artifacts (Plate 48). These features are located as follows: on the collar (n=3); on the neck (n=13); and on the body (n=9). Four additional unanalyzable fragments have mend holes, and two artifacts have mend hole attempts on the neck.

While fingerprints were identified on fifteen artifacts, no attempt was made to analyze them. They have been documented here to facilitate future study. Fingerprints appeared on ten pieces of miscellaneous fired clay, one neck fragment, one neck, shoulder and body fragment, one unanalyzable fragment and two vessels of the Niagara Collared (Cat. #9228) and Huron Incised (Cat. #12331) types, respectively.

Plate 48: Partial Mend Hole

### 3.2 Ceramic Smoking Pipes

The Mantle ceramic smoking pipe assemblage is comprised of 548 fragments. Pipe stem, elbow and mouthpiece fragments represent a little more than half (57.66%) of the assemblage, while bowl fragments account for 42.34% (Table 36).

**Table 36: Pipe Assemblage**

Condition	n	%
Identifiable Bowl Fragments	146	26.64
Stem Fragments	133	24.27
Unidentifiable Bowl Fragments	86	15.69
Elbow Fragments	79	14.42
Stem and Elbow Fragments	39	7.3
Stem with Mouthpiece Fragments	37	6.75
Stem with Mouthpiece to Elbow Fragments	22	3.83
Mouthpiece Fragments	3	0.55
Indeterminate Pipe Fragments	3	0.55
<b>Total</b>	<b>548</b>	<b>100</b>

Surface burnishing in varying degrees is identified on 403 fragments (73.54%). Twenty-one fragments are classified as indeterminate due to exterior surface weathering or exfoliation, one is untreated and rough, and the remainders are classified as smoothed (22.45%).

#### 3.2.1 Bowl Fragments

The identified smoking pipe types are itemized in Table 37 below.

**Table 37: Ceramic Smoking Pipe Types**

Bowl Type	n	%
Coronet	25	17.12
Trumpet Plain	17	11.64
Trumpet Decorated	15	10.27
Conical Plain	12	8.22
Apple Bowl Ring	12	8.22

<b>Type</b>	<b>146</b>	<b>99.95</b>

### Coronet

Twenty-five pipe bowls are classified as Coronet. These pipes display a collar height that ranges from 7.52 to 22.6 mm with a mean of 12.1 and a standard deviation of 3.88. Lip thickness ranges from 4.99 to 14.54 mm with a mean of 7.4 and a standard deviation of 2.21. Exterior bowl diameters were obtained from four pipes, and these measured 44.15, 37.69, 37.36 and 34.73 mm.

Table 38 summarizes the twenty different combinations of motif and technique found on the collars of Coronet pipes. Four pipes lack the typical punctate or groove encountered on corners of the squared collar. Plate 49 illustrates a Coronet pipe fragment (Cat. #12387) recovered from Midden 1 that includes a copper insert in one of the corner notches. Other examples of Coronet pipes are illustrated in Plate 50.

**Table 38: Coronet Pipe Motifs and Techniques**

<b>Total</b>		<b>25</b>	<b>100.00</b>

Plate 49: Coronet Pipe with Copper insert (Cat. #12387)

Plate 50: Coronet Pipe, (Cat. #12310 and Cat. #12295)

***Trumpet Plain***

Seventeen pipe bowl fragments are classified as Trumpet Plain. Lip thickness ranges from 2.72 to 21.43 mm with a mean of 8.52 and a standard deviation of 5.01.

Bowl diameters were obtained from three specimens, which measured 36.39, 38.89 and 40.07 mm, respectively. One nearly complete pipe (Cat. #12278) recovered from Midden 1 has a bowl diameter of 23.86 mm with a bowl height of 51.92 mm (Plate 51). Red pigment was noted on the bowl exterior and lip of one pipe recovered from the backdirt (Cat. #12157).

Plate 51: Trumpet Plain, (Cat. #12278 and Cat. #118311)

***Trumpet Decorated***

Sixteen pipes are classified as Trumpet Decorated. Slight collars with some decoration are identified on fourteen of these pipes. The collar height ranges from 5.61 to 11.47 mm, with a mean height of 7.66 and a standard deviation of 1.61. Three motifs are identified on the collars of these pipes, and they consist of: a single horizontal incised or punctated line (n=6); a simple band of oblique or vertical lines that may be interrupted (n=4); or a simple incised horizontal line inlaid with a band of linear stamped vertical lines (n=4).

Lip thickness could be measured for twelve specimens and ranged from 2.7 to 13.78 mm, with a mean of 8.73 and a standard deviation of 3.76. An exterior bowl diameter was obtained from one specimen, which measured 46.44 mm. One pipe typed as Trumpet Decorated exhibits decoration on the lip consisting of an incised geometric pattern, and examples of Trumpet Decorated pipes are shown in Plate 52.

Plate 52: Trumpet Decorated, (Cat. #12262 and Cat. #12268)

### ***Conical Plain***

There are twelve Conical Plain pipe fragments in the assemblage, and nine of these specimens have a flared lip. Lip thickness ranges from 2.97 to 9.05 mm, with a mean of 5.29 and a standard deviation of 1.46. An exterior bowl diameter was obtained from one specimen (30.55 mm). A lip motif consisting of a simple band of linear stamped oblique lines is identified on specimen 118181. Evidence of a partially reworked port is identified on the lower bowl of one specimen (Cat. #118261).

### ***Apple Bowl Ring***

Twelve of the bowl fragments from the Apple Bowl Ring type exhibit complete motifs (Table 39).

Table 39: Apple Bowl Ring Decorative Motifs

Decorative Motif	n	%
Horizontal (7) over Punctate	1	8.33
Horizontal (7)	1	8.33
Horizontal (4+) over Unknown	1	8.33
Horizontal (4)	2	16.67

Horizontal (3)	1	8.33
Horizontal (2+) over Unknown	2	16.67
Horizontal (2)	2	16.67
Total	12	99.99

Apple Bowl Ring pipes from Mantle have lip thicknesses ranging from 1.25 to 8.01 mm, with a mean of 4.57 and a standard deviation of 2.2; one bowl diameter of 25.87 was obtained. Examples of this pipe type are shown in Plate 53.

Plate 53: Apple Bowl Ring, (Cat. #12226 and Cat. #12245)

### ***Mortice***

Twelve pipes are identified as Mortice, and these display different motifs and decorative techniques (Table 40).

**Table 40: Mortice Motifs and Decorative Techniques**

<b>Motif</b>	<b>Decorative Technique</b>	<b>n</b>	<b>%</b>
Horizontal (1) inlaid with Punctates over Vertical over Horizontal (1) inlaid with Punctates	Incised inlaid with Punctates over Grooved over Incised inlaid with Punctates	3	25.00

<b>Total</b>		<b>12</b>	<b>99.98</b>

Collar height could be measured on nine specimens, and ranges from 15.68 to 33.98 mm with a mean of 22.57 and a standard deviation of 6.09. Lip thickness (n=10) ranges from 3.68 to 11.83 mm, with a mean of 7.66 and a standard deviation of 2.82. An exterior bowl diameter was obtained from one specimen (31.54 mm).

One pipe recovered from Feature 146 (Cat. #118491) displays a reworked port on the lower bowl. Examples of Mortice pipes are illustrated in Plate 54.

Plate 54: Mortice, (Cat. #118461 and Cat. #12247)

### ***Conical Ring***

Eight pipes are identified as Conical Ring, and Table 41 provides the motif attributes (including the number of horizontal bands encountered on the bowls).

**Table 41: Conical Ring Motifs**

<b>Decorative Motif</b>	<b>n</b>	<b>%</b>
Horizontal (7+) over Unknown	1	12.5
Horizontal (7)	2	25
Horizontal (6)	1	12.5
Horizontal (5)	3	37.5
Horizontal (4)	1	12.5
<b>Total</b>	<b>8</b>	<b>100</b>

Lip thickness was obtained from nine specimens and ranged from 3.92 to 9.82 mm, with a mean of 5.36 and a standard deviation of 2.15. An exterior bowl diameter was obtained from two specimens measuring 34.99 mm and 31.8 mm, respectively. Bowl height was recorded from one specimen (55.9 mm).

### ***Collared Decorated***

Six Collared Decorated pipes were recovered, and they display a horizontal motif of one to seven incised lines on a collar. An additional incised horizontal line was identified on the lip of one pipe (Cat. #12213).

Collar height ranged from 4.78 to 29.95 mm with a mean of 16.32 and a standard deviation of 8.6. Lip thickness ranged from 4.75 to 8.9 mm, with a mean of 6.42 and a standard deviation of 1.60. Exterior bowl diameters were obtained from two specimens, which measured 28.65 and 34.99 mm, respectively. Examples of Collared Decorated pipes are shown in Plate 55.

Plate 55: Collared Decorated, (Cat. #12214 &amp; Cat. #12215)

### ***Barrel Plain***

Five pipe bowls are classified as Barrel Plain. These bowls are plain with lip thickness ranging from 1.55 to 6.54 mm, with a mean of 3.37 and a standard deviation of 1.99. One small specimen (Cat. #12277) has an oval bowl diameter and measures 13.98 mm in width by 11.17 mm in length.

### ***Iroquois Ring***

Three pipes are classified as Iroquois Ring. The first specimen (Cat. #12217) has a lip thickness of 3.99 mm with a bowl decorated by six or more incised lines. The second bowl (Cat. #12236) has a lip thickness measuring 3.24 mm and decoration consisting of four or more incised lines. The last pipe (Cat. #12242) has a lip thickness of 3.17 mm and has a decorative motif of six incised lines over a horizontal band of punctates.

### ***Collared Decorated***

Three pipes are classified as Collared Decorated. The first specimen (Cat. #12246) has a lip thickness of 6.01 mm and a collar height of 17.89 mm, and is decorated with four incised lines separated by single band of punctates. The second bowl (Cat. #12266) has a lip thickness of 7.75 mm, a collar height of 13.75 mm, and is decorated by a single band of punctates at the top and bottom of the collar. The third pipe (Cat. #12347) has a lip thickness of 4.53 mm, an exterior bowl diameter of 37.77 mm, and a collar height of 11.93 mm. The collar is decorated by two alternating bands of oblique lines manufactured by punctates over incised horizontal lines.

### ***Conical Decorated***

There are two Conical Decorated pipes in the assemblage. The first specimen (Cat. #12271) has a lip thickness of 6.22 mm and is decorated with a frontal lip motif consisting of a simple band of stamped oblique lines. The other (Cat. #12273) displays a short decorative band on the upper bowl consisting of an

opposed motif of incised left and right oblique lines. The lip measures 6.1 mm and is decorated by a row of intermittent punctates.

### ***Apple Bowl Decorated***

The single specimen (Cat. #12270) classified as Apple Bowl Decorated has a lip thickness of 3.83 mm and has a partial decorative motif consisting of a mix of incised oblique, vertical lines interspersed with punctates.

### ***Collared Plain***

The one Collared Plain specimen (Cat. #12349) has a collar height of 16.62 mm with a partial drill hole through the collar.

### ***Disc***

A single disc pipe (Cat. #12388) has a disc radius of 35.4 millimetres from the edge of the central hole and is 9.3 millimetres thick at its edge (Plate 56). These measurements render this specimen quite unlike flattened trumpet pipes, which are far smaller and thinner although admittedly the diameter of the hole on this piece at approximately 21 millimetres is significantly larger than those found on most stone pipes. The design on the piece is also unique and consists of zoned opposed incised oblique lines meeting at a central vertical line alternating with blank triangles bordered by rows of small punctuates. The surface of the artifact is washed with a red coloured pigment. For further discussion of the pigment wash see Section 3.5.

Plate 56: Disc pipe (Cat. #12388)

### ***Cylindrical Decorated***

The one Cylindrical Decorated pipe (Cat. #12269) has a lip thickness of 5.7 mm and a decorative motif consisting of a band of incised oblique lines crossed by two incised horizontal lines. The lip is decorated by a band of linear punctates with vertical stamped lines on the frontal lip.

### ***Untyped***

These three bowls exhibit motifs and shapes that did not correspond to any particular type. The first specimen (Cat. #12158) has a lip thickness of 9.02 mm and plain square profile. The second specimen (Cat. #512159) has a ground lip, a bowl thickness of 1.91 mm and a plain exterior. The third specimen (Cat. #12211) exhibits a flat facet with an incised horizontal line just under the lip. The lip measures 5.8 mm in thickness.

### ***Effigies***

Effigies account for 13.01% of the total pipe assemblage. This includes eight anthropomorphic effigies, four zoomorphic effigies and seven effigies that are typologically indeterminate. Additionally, two pipe stem fragments also display possible partial effigy motifs.

The seven effigies classified as Anthropomorphic are incomplete fragments, but represent obvious facial features. Specimen Cat. #12317 displays a single slit eye and a plain lip and was recovered from Feature 1044. Another fragment (Cat. #12319) displays a naturalistic partial nose and slit mouth and was recovered from the surface on the southeastern portion of the site. Specimen Cat. #12320 consists of a naturalistic partial nose and partial slit eye and was recovered from Unit 480-170.

Specimen Cat. #12356 consists of a partial recessed eye, which is emphasized by a single row of punctates to the exterior of the socket. A partial incised arching line is present where the eye should be. The crest of the forehead is decorated by a single row of punctates. This artifact was recovered from Unit 504-156.

Specimen Cat. #12316 represents a portion of recessed eye socket with a slit eye and a portion of an incised open mouth. The forehead and lip are plain and the portion of a groove that is typically associated with the Mortice typed pipes is located where one would suspect the ear to be. This artifact was recovered from Post mould 15 in Unit 520-245 (Plate 57).

Plate 57: Anthropomorphic Effigy  
(Cat. #12316)

One of the more complete effigy fragments, specimen Cat. #12318, was recovered from the surface at the southern limit of the site. This bowl of the pipe represents the mouth of the anthropomorphic face, and the facial features are incorporated on the lip. The nose is incomplete but appears to be naturalistic, while the forehead is exaggerated, creating deep recesses for the eyes. The eyebrows are decorated by series of vertical linear stamped lines (Plate 58).

Plate 58: Anthropomorphic Effigy (Cat. #12318)

Specimen Cat. #12350 consists of half a human effigy face. The effigy emphasizes three attributes: recessed eyes sockets; a developed chin and mouth; and a horizontal projection to the back of the head. The face is surrounded by a single row of punctates that dips between what would have been the two horizontal projections. Within the eye sockets, the eyes are raised and impressed in the centre. The nostrils are represented by two punctate holes, while the mouth is constituted by a horizontal row of punctates with an over-emphasized chin. The nose appears to be naturalistic but quite large. The remainder of the bowl is decorated by several bands of punctates that may depict hair. This artifact was recovered from Feature 382 and the encircling dotted pattern may reference tattooing (see Birch and Williamson 2013) (Plate 59).

Artifact Cat. #12351 is the only complete effigy face (Plate 60). The effigy emphasizes three attributes: recessed eyes sockets; developed chin mouth; and a single notch in the forehead. The slit eye and mouth appear open. The nose appears to be naturalistic but large with two punctates representing the nostrils. The face appears to protrude slightly from the rest of the bowl, and the pair of vertical grooves present behind the head is typically associated with Mortice pipes. This artifact was recovered from Midden 1, Unit 496-119.

Plate 59: Effigy Anthropomorphic (Cat. #12350)

Plate 60: Effigy Anthropomorphic (Cat. #12351)

Four pipe bowl effigies are classified as Zoomorphic. Three are relatively complete while the fourth is fragmentary.

One pipe bowl (Cat. #12352) probably depicts a pileated woodpecker with its long beak and crested head (Plate 61). This artifact is well burnished and displays post-firing grinding of the sides of the crest, and notches at the peak of the crest and the eyes. Scratching was employed to shape the partition of the mouth. This artifact was recovered from Post mould 1 in Unit 360-165.

Plate 61: Effigy Zoomorphic (Cat. #12352)

Specimen Cat. #12353 is a naturalistic portrayal of an owl with a short beak, large eyes and a radiating row of feathers around its head (Plate 62). The eyes are formed by deep depressions, while the beak is molded and incised. A single incised line and a band of short stamp lines that encircle the face and run along the lip of the bowl represent the radiating row of feathers. This artifact was recovered from Post mould 23 in unit 550-170.

Plate 62: Effigy Zoomorphic (Cat. #12353)

Another zoomorphic pipe (Cat. #12354) is an open mouth turtle, snake or bird effigy. The pipe is well burnished and is missing the lower beak. The eyes are ground and were made after firing. This artifact was recovered from Midden 1 Unit 498-120 (Plate 63).

Plate 63: Effigy Zoomorphic (Cat. #12354)

Effigy fragment Cat. #12357 depicts a small portion of a beak belonging to a bird or turtle open mouth effigy pipe (similar to artifact Cat. #12354 above). This artifact was recovered from Feature 986, Quadrant 1.

The remaining seven effigies are classified as indeterminate, exhibiting characteristics that identify them as effigies but lacking diagnostic traits for more precise classification.

Specimen Cat. #12322 displays an upper bowl scar where an effigy was once situated. Partial motifs of incised horizontal lines are visible on the remainder of the bowl. This artifact was recovered from Feature 55.

Another pipe (Cat. #12323) exhibits a molded surface that is decorated by a band of punctates that runs down the pipe bowl. This artifact may represent a limb of a squatting or kneeling figure. This artifact was recovered from Feature 709 and is illustrated in Plate 64.

Plate 64: Effigy Indeterminate (Cat. #12323)

One nearly complete pipe (Cat. #12348) exhibits a bowl motif of eleven incised lines that stop under a molded lip and probable effigy scar. The combination of the plain and molded surfaces suggests that an effigy once occupied this space. This artifact was recovered from Feature 709.

Indeterminate effigy fragment Cat. #12355 displays a smooth molded surface that is bounded on the exterior by a single row of punctates. This artifact was recovered from Unit 490-187.

Another pipe fragment (Cat. #12361) exhibits a plain trumpet type shape with a flat facet and a single punctate before the break. Traces of red ochre are present on the exterior of the bowl. This artifact was recovered from the surface on the western limit of the site.

Indeterminate effigy fragment Cat. #12362 displays a partial bowl motif of incised oblique and horizontal lines. Grinding is present on a molded lip. This artifact was recovered from Unit 457-125.

The final specimen (Cat. #12280) is well polished, plain and molded. This artifact was recovered from Feature 986, Quadrant 2.

### ***Unidentifiable Bowl Fragments***

One unidentifiable bowl fragment (Cat. #12360) from Feature 709 has an indeterminate motif on the collar and a partial hourglass symbol on the lip.

### **3.2.2 Stem Effigy Fragments**

Two pipe stem fragments recovered from the surface exhibit a possible coiled snake effigy on the stem. The first (Cat. #12358) is decorated by two rows of punctates on a coiled molded surface. The other (Cat. #12342) displays a molded band at an oblique angle to the stem and is decorated by stamped lines. This fragment also displays possible grinding at one end.

### **3.2.3 Elbows and Stems**

Three hundred and ten stem and elbow fragments are present in the assemblage. Decorative motifs are identified on one stem and two elbow fragments, and consist of decorations such as an indeterminate etched motif or a single horizontal row of punctates along a lateral edge.

### **3.2.4 Mouthpieces**

Mouthpieces are mostly ground (n=25), but tapered (n=21), bulbous (n=15) and flared (n=1) ones were also recovered (Table 42). Of the mouthpieces identified in the assemblage, forty-six are sufficiently complete to obtain data on borehole diameters (Table 43).

**Table 42: Mouthpiece Types**

<b>Mouthpiece Type</b>	<b>n</b>	<b>%</b>
Ground	25	40.32
Tapered	21	33.87
Bulbous	15	24.19
Flared	1	1.61
<b>Total</b>	<b>62</b>	<b>99.99</b>

**Table 43: Mouthpiece Borehole Diameters (n=46)**

Mean	3.54
Range	1.51-6.1
Standard Deviation	1.02

### 3.2.5 Ceramic Beads

Three ceramic beads made from pipe stem fragments are present in the collection. Artifact Cat. #11491 is a stem and mouthpiece fragment of the tapered type. It is ground on the opposite end and measures 21.62 mm (Plate 63). Stem fragments Cat. #11645 and Cat. #12183 display grinding on both margins and measure 22.43 and 16.79 mm, respectively.

Plate 65: Beads (Cat. #12183, Cat. #11491 and Cat. #11645)

## 3.3 Juvenile-Manufactured Ceramic Vessels and Pipes

*Alexsandra Pradzynski*

### 3.3.1 Introduction and Overview

Children were active participants in all past societies. Childhood was not only a time of innocent play, but also the time to learn the valuable life skills that are needed to survive as adults. Children played a valuable and constructive role in the cultural and economic spheres of past populations. Thus, in order to have a better understanding of the structure of ancient societies, it is important to include children in analyses (Kamp 2001a; Ruttle 2010; Smith 2005). Studying juvenile ceramics may therefore shed some light on children's lives, including such things as their daily activities and learning processes.

The most common juvenile artifacts recovered from the Mantle site are ceramic fragments. The criteria used to distinguish juvenile ceramic vessels from those of adults include the crudeness of form, vessel size, decorative motifs and techniques used. Ceramics made by children are usually pinch pots, small and/or asymmetrical vessels that exhibit uneven vessel thickness, a roughly finished surface, and drying cracks. Such lumpy and irregular vessels would have been functionally poor, although they serve as indicators of the transmission of knowledge and skill, and the process of producing them indicates that children were creative pottery makers (Kamp 2001b; Smith 2005).

**Table 44: Mantle Site, Juvenile Ceramic Artifacts**

<b>Type</b>	<b>n</b>	<b>%</b>

Shoulder Fragment	8	1.08
Miscellaneous	3	0.4
Base Fragment	1	0.14
<b>Total</b>	<b>741</b>	<b>100</b>

Seven hundred and forty-one ceramic artifacts were identified as juvenile-manufactured ceramic vessels and pipes (Table 44). In general, most ceramic vessels and other ceramic fragments had their exterior surfaces at least partially smoothed. Clear fingernail and partial fingertip impressions left during the process of creating pots are visible on interior and exterior surfaces. Numerous vessels exhibit small drying cracks, most of which are on the interior surfaces.

A large portion of the juvenile ceramics have no temper (47.50%), while sand (<2 mm) is also noted as temper in a substantial proportion of the sample (40.08%). In addition, grit (>2mm) was added as temper to 5.13% of the juvenile assemblage, while a combination of sand and grit was observed in 6.75% of the sample. Four vessels exhibited the use of sand and mica as temper.

### 3.3.2 Juvenile Ceramic Vessels

#### *Juvenile Vessel Rims*

Juvenile rims were analyzed using an attribute approach. They were regarded as analyzable if they exhibited interior and exterior surfaces, a lip, and a sufficient portion of the exterior collar-neck area to identify the decorative motif and associated attributes. The rim sample was sorted and mended into 193 individual vessels. Summary descriptive statistics of individual attributes are presented in Table 45. Seven vessels are represented by castellation fragments only, and are not included in the following discussion.

In addition to identified vessel rims, 165 rim fragments are included in the juvenile ceramic sample. Due to their fragmentary nature, they do not provide reliable data and are not included in this analysis.

Table 45: Summary of Formal Attributes for Juvenile Vessels (n=186)

			<b>Total</b>	<b>186</b>	<b>100</b>

The majority of juvenile rims have either an incipient collar (40.32%) or a well-developed collar (26.34%), while collarless vessels comprise 33.33% of the sample. The collar bases are rounded for almost all collars present (n=123), while only one was angular. The vessel collar heights are between 4.09 mm and 43.10 mm, with an average of 12.10 mm and a standard deviation of 6.36. The basal collar widths range from 3.06 mm to 15.82 mm, with a mean of 7.19 mm and a standard deviation of 1.95.

Most vessels have a rounded lip (88.17%), while flat (9.14%), irregular (1.61%) and pointed (1.08%) lips are also present in lower frequencies. The angle of the lip-to-interior is predominantly obtuse (95.16%), with a minority of vessels exhibiting acute (3.76%) and right (1.08%) angles. Lip thickness ranges between 1.00 mm and 10.18 mm with a mean of 4.06 mm and a standard deviation of 1.51.

Most vessels have a rim orientation that is outflaring (63.98%), while smaller numbers of vessels have a rim orientation that is insloping (22.58%) or vertical (13.44%).

Interior profiles are convex (81.18%), concave (11.29%), straight (6.99%) and concave/convex (0.54%). The exterior profiles of the vessels are convex (89.78%), concave (6.45%), straight (3.24%) and convex/concave (0.54%).

The vessel interior is usually plain (98.39%) and the only decorative motifs on interiors are obliques (1.61%). Interior decorative techniques include fingernail impressions (0.54%), incising (0.54%), and linear stamping (0.54%).

In most cases, lips are plain (79.57%). Decorated lip motifs include oblique (9.67%), notching (7.53%), punctates (2.15%), obliques crossed by obliques (0.54%) and opposed (0.54%) (Plate 66). Notching is the most common technique used for decorating the lip (7.53%), (Plate 67). Other utilized techniques include incising (6.45%), linear stamping (2.68%), punctates (2.15%), finger impressions (1.08%) and incising crossed by incising (0.54%).

Plate 66: Juvenile Vessels (left to right): Cat. #13066, Cat. #13056, Cat. #13147, Cat. #13068 and Cat. #13127

<b>Total</b>	<b>186</b>	<b>100</b>	<b>Total</b>	<b>186</b>	<b>100</b>

Tables 46 and 47 summarize the exterior surface decorative attributes for vessel collars and necks. Plain collars dominate the sample (63.44%). The most common decorative motifs on decorated collars include oblique (18.81%), punctate (5.91%), plain/ oblique (2.15%), opposed (1.61%), notch (1.07%) and oblique/oblique (1.07%). The rest of vessels include single examples of decorative motifs and their combinations. The most common decorative technique on decorated collars is incising (11.29%), followed by punctates (6.98%), fingernail impressions (5.37%), linear stamping (4.84%) and notching (1.07%) (Plate 68). The remaining vessels exhibit a combination of a variety of different techniques.

The exterior surfaces of necks tend to be plain (83.33%), while oblique (8.6%), horizontal (4.84%), punctate (1.61%), oblique crossed by oblique (1.08%) and interrupted horizontal (0.54%) motifs are present in minority frequencies. Decorative techniques include incising (10.75%), punctates (2.69%), linear stamping (2.15%), fingernail impressions (0.54%) and fingernail impressions crossed by incising (0.54%).

**Table 47: Summary of Decorative Attributes of Necks for Juvenile Vessels**

<b>Total</b>	<b>186</b>	<b>100</b>	<b>Total</b>	<b>186</b>	<b>100</b>

Plate 67: Juvenile Vessel with notched lip (Cat. #13039)

Plate 68: Juvenile Plain Vessel (Cat. #10999)

The juvenile vessels in the Mantle assemblage are largely plain (Plate 68) or poorly decorated, yet it is still possible to make a few interesting observations regarding decorative patterns. A superficial examination based on pot manufacture and decoration suggests that young potters tended to copy the motifs and techniques used to manufacture adult pots. However, since juvenile pots were usually too small to be used in daily activities, it is believed they were used by children as toys (Kamp, 2001b).

### ***Neck Fragments***

One hundred and forty-nine neck fragments are identified in the assemblage either as isolated fragments or in combination with the shoulder and body. One hundred and fourteen neck fragments are plain (76.5%), 34 neck pieces are decorated (22.8%), and a single specimen was smoothed over ribbed paddle (0.06%).

### ***Shoulder Fragments***

One hundred and eleven shoulder fragments are identified in the assemblage either as isolated fragments or associated with the neck and body. All shoulder fragments are rounded. There are 75 plain shoulder fragments (67.5%) and 36 decorated shoulder fragments (32.5%).

### ***Body Fragments***

Out of 171 body fragments, 136 sherds are plain (79.5%). Thirty-four body sherds were decorated (19.9%) and in two instances, the exterior surface has been smoothed over ribbed paddle (0.01%). The exterior surface of one body sherd is untreated.

### ***Castellations***

Eleven juvenile castellations were recovered from the site. Four castellations are associated with previously analyzed vessels, while the remaining seven are isolated fragments. The castellations are mostly rounded ( $n=8$ ), (Plate 69), but single examples of pointed, multiple rounded and pinched shapes are also present. Eight castellations are plain, and the remaining three specimens are decorated with

punctates (n=2) and incised obliques (n=1). The surface of one castellation is burnished and features an apparent red pigment.

Plate 69: Juvenile Vessel with rounded castellation (not all fragments shown) (Cat. #10995)

### ***Miscellaneous***

Three miscellaneous ceramic artifacts are present in the juvenile-manufactured ceramic sample. One of them is an untempered and unfired lump of clay. Another object is also a lump of clay, but fired and tempered with sand. The third miscellaneous artifact is an unfired flattened clay fragment that had been tempered with sand. It was probably part of a broken strap handle.

### **3.3.3 Juvenile Ceramic Smoking Pipes**

The analysis of juvenile smoking pipes was conducted in the same manner as the adult pipes, with the bowl and orifice diameter, thickness of the stem, borehole diameter, and description of decorative motif, decorative technique, bowl form and stem form noted. Other observations include the description of the surface treatment, nature of inclusions (if any), and pipe utilization.

The juvenile ceramic pipes consist of five stem and mouthpiece fragments, four identified bowls, four unidentified bowls, and one elbow.

Three stem fragments had their exterior smoothed, with two roughly smoothed, and one stem slightly burnished. One stem fragment has no borehole. The shape of the mouthpiece could be identified for three specimens, all three of which are tapered. The bore diameter could be measured for one stem with mouthpiece, at 6.26 mm. Two stem fragments were tempered with sand, one with grit, and one had no temper.

The single elbow fragment in the assemblage lacks a borehole, has a smoothed exterior, and contains sand inclusions.

The exteriors of all eight identified and unidentified bowl fragments are smoothed. All four identified bowl fragments are plain, two of which have an outflaring exterior bowl orientation (Plate 70), with the remaining two vertically oriented. Bowl height could be measured for two specimens, which are 22 mm and 11.38 mm respectively. Bowl diameter could be measured for three artifacts, with specimens

measuring 15.97 mm, 19.28 mm and 21.83 mm. Orifice diameters were also measured for the same bowl fragments, and these measure 13.54 mm, 11.89 mm and 19.81 mm respectively. A single pipe bowl is collared and has a pentagonal shape (Plate 71). Five bowl fragments were tempered with sand, and three bowl fragments had no temper.

Plate 71: Juvenile Outflaring Pipe (Cat. #13185)

Plate 70: Juvenile Pentagonal Pipe (Cat. #13186)

Since juvenile pipes are rarely functional and show no evidence of having been smoked, it is very likely that pipes manufactured by young potters were used by children “as toys or trial pieces” (von Gernet 1985:137).

### 3.3.4 Intra-Site Distribution of Juvenile Ceramics

Table 48 outlines the distribution of juvenile ceramic vessels and pipes among major provenience units. Juvenile ceramics were mostly recovered from midden contexts. A large portion of juvenile artifacts was also recovered from exterior features and in House 15 and House 16. There are no juvenile ceramic mends between different features and middens.

### 3.4 Inter and Intra-Site Distribution of Ceramic Types and Attributes

*Robert B. Wojtowicz, Alessandra Pradzynski, Jennifer Birch and Ronald Williamson*

#### 3.4.1 Chronological Sequence

Reconstruction of the chronological sequence of community relocations that led to the Mantle site occupation is a complex process involving various lines of evidence. Interpreting this sequence based on ceramic data alone is problematic due to variations in the amount of data available for comparison and the typologies and attribute descriptions used by different authors. These limitations notwithstanding, subtle differences in temporal sub-assemblage composition indicate that the population inhabiting the Mantle site formerly occupied the late 15<sup>th</sup> century Draper and Spang sites (see Birch 2010; Birch and Williamson 2013).

There is evidence of a long history of Iroquoian settlement in the Rouge-Duffins Creek drainage. By the early fifteenth century, there were eight village sites on West Duffins Creek and its tributaries including (from west to east), the Dent Brown, Robin Hood, Wilson Park, Best, White, Carruthers, Pugh and Gostick sites (Poulton 1979). This increase in local site density was a part of the general pattern of regional population growth occurring during the late fourteenth to early fifteenth century (Warrick 2008:181-185; Birch and Williamson 2013, see Chapter Two).

Social and political networks certainly existed between the West Duffins Creek communities. All lived within an area of twenty-five square kilometers, with some villages located less than two kilometers apart. Their proximity suggests that these people would have encountered each other in adjacent horticultural fields and would also have shared overlapping hunting, fishing and gathering territories. They also likely participated in exchange systems, some of which may have involved co-operative trade and/or procurement of resources only available at some distance from the local area (for example, Onondaga chert from the Niagara Peninsula). These activities would have created close ties between these populations (see Spence 1999). Shared religious practices and a common ideology that included ossuary burial (Williamson and Steiss 2003), a distinct ancestral Wendat mortuary practice, would have also helped to engender a sense of common identity. These interactions and associations undoubtedly would have laid the foundations for negotiating coalescence. By the mid-to-late fifteenth century, these small villages were all abandoned, their populations presumably aggregating at the nearby Draper site (Finlayson 1985; Warrick 2000:449).

It is possible that the Best site was occupied into the mid-fifteenth century, contemporary with the early phases/expansions of the Draper site (Warrick 2008:137). Some similarities in ceramic development among the Best, Draper and Spang assemblages also parallel more general, regional trends identified in the 15<sup>th</sup> century (Tables 49 and 50).

While generally, the Draper site assemblage has more variety and includes more exotic vessels, the most obvious difference among the three sites is the lower frequency of Huron Incised in the Draper assemblage. Yet in examining the attribute of neck decoration, over the course of the occupation and expansion of the village, the percentage of plain necked vessels changes from 35.5% in the earliest occupation area to close to 60% in the last addition to the main village. This difference is statistically significant ( $\chi^2=38.6$ ,  $p = 0.05$ ,  $df = 1$ ). In that plain necks increase in time, the frequency of this attribute is nearly identical in the Draper Site South Field (47.4%) and at the Best site (47.8%), lending support to Warrick's (2008:137) suggestion that Best represents the sixth and final addition to the Draper community.

The relative frequencies of exotic types from either the New York Iroquois or the St. Lawrence Iroquoians differ among the Best, Spang and Draper site ceramic assemblages. The Best and Spang site assemblages contain low frequencies (3.7 and 2.9% respectively) of St. Lawrence Iroquoian ceramics and no ceramic types necessarily originating in New York State given the regular presence of Dutch Hollow Notched and Onondaga Triangular vessels on fifteenth century ancestral Huron sites. Other fifteenth century sites including Pugh, Carruthers, Wilson Park, Gostick and Robin Hood contain neither St. Lawrence Iroquoian types nor any of those believed to originate in New York State, suggesting a slightly earlier fifteenth century occupation (Tables 51 and 52) for them. The difference may result from fluctuations in interaction with St. Lawrence Iroquoian groups, which appear to have been more active in the Duffins Creek drainage in the mid-to late fifteenth century. Additionally, sub-groups within the Draper village may have had closer ties with Eastern Iroquoian groups, a proposition supported by the fact that Expansion 4 and 5 yield the highest frequencies of St. Lawrence attributes currently documented in the West Duffins Creek site sequence. A similar pattern was noted for the eastern segment of the excavated area at the Parsons Site (Robertson and Williamson 1998:147).

Although great effort was taken to isolate the ceramic material from each of the expansions at the Draper Site, it is difficult to draw meaningful links between each expansion at Draper and the sites from which these populations may have originated (Table 53). Nevertheless, the attributes observed in ceramics from the original part of the Draper site and Expansions 1 through 3 do display some of the lowest frequencies of plain neck motif and frontal lip notching during the village development (both of which are attributes thought to have developed late in the fifteenth century).

There is currently little information available about the Dent Brown and Carruthers sites. Data available for the Dent Brown site indicate that 71.4% of the vessels had plain interiors and 75% of the vessels had simple collar motifs. A little less than half (45.8%) of the isolated neck fragments are decorated. Even less data are available for the Carruthers site, whose assemblage includes three Huron Incised and two Black Necked vessels with plain interior motifs. Additionally, 72.23% of the isolated neck fragments are plain. The Robin Hood site assemblage was documented by Williamson (1983). It consists of Huron Incised (42.11%), Lawson Incised (10.53%) and Black Necked (47.37%) types. Interior motifs are associated with 9.5% of the vessels. Neck decorations are identified on 40% of the isolated fragments. Another nearby site, Wilson Park, has yielded predominantly necked vessels and it is not yet known how the site relates to the others forming the Draper community. It has yet to yield any evidence of interaction with St. Lawrence or Iroquois communities.

	Neck Plain	46.4	51.69	89.55

The Mantle site ceramics assemblage clearly postdates Draper and Spang with significantly more plain necks. There is also clear evidence of interaction between Mantle and groups from New York (3.13%). The recovery of Cayadutta-Otstungo Incised and Chanced Incised ceramics with three-dimensional effigies implies that a portion of that interaction was specifically with groups living in territories associated with either the Oneida or Onondaga Iroquois. Several vessels were also identified as St. Lawrence types, including Durfee, Roebuck Low Collared and Corn-Ear types.

In terms of variation within the Mantle community over time, in the early and late phases of the village's occupation there are no major differences in the frequencies of types or attributes between early and late phases of the village's occupation (Tables 55 and 56). The exception to this is that the late village assemblage displays a slightly lower frequency of plain lip and slightly higher concave interior profiles than the earlier assemblage, but these differences are not statistically significant.

The Aurora site, a 3.4 ha village also known as “Old Indian Fort” and thought to be one of the possible successor villages of the Mantle site, was investigated by the University of Toronto (Emerson 1954:165). It is situated at the top of a steep-sided hill overlooking a small stream at the headwaters of the East Holland River. The initial excavations carried out by the University of Toronto in 1947 yielded charred corn kernels, discoidal stone beads, tubular bone beads, about a dozen stemmed, notched and triangular chert arrow points and an assortment of castellated pottery. While they did not find any European trade goods, later surface collections produced a piece of copper which has yet to be tested. Recent re-analyses of the ceramics from the site seem to place its occupation in the mid-sixteenth century (Table 57; also Pihl et al. 2011, Ramsden 1977:65). It is notable that the palisade surrounding the site included an earthen embankment, which was also a feature of the final phase of palisade construction at the Mantle site.

**Table 57: Inter-Site Attribute Comparison Mantle and Aurora**

	Attribute	Mantle	Aurora
Interior Profile	Concave	11.76	2.48
	Convex	80.62	90.91
	Straight	7.52	6.61
Exterior Profile	Concave	56.37	67.77
	Convex	36.94	28.1
	Straight	4.39	3.31
	Interior Plain	90.65	92.56
	Lip Plain	63.27	73.34
	Undecorated	7.05	9.09

	Neck Plain	89.55	95.04

Ceramic type frequencies at Mantle and Aurora are fairly consistent with the overall ceramic trends identified within the fifteenth century; specifically the continued increase in the frequency of plain-necked ware such as the Huron Incised and Sidey Notched types (Table 58). The near absence of foreign New York types on the Aurora Site is of interest as it may indicate that a regionally significant political shift took place in terms of interaction with far distant communities.

### 3.5 Pigment Analysis

*Andrea Carnevale and Brandi Lee MacDonald*

Red pigment staining was identified on 131 ceramic vessel fragments and one identifiable vessel of the High Collar (Cat. #9233) type. Red pigment was observed on the interior (51.91%) and exterior (46.58%) of the artifacts, with two fragments displaying staining on both the interior and exterior. Thirty-nine vessel fragments from Unit 524.5-141.5 (Cat. #1474, Cat. #1477 and Cat. #1478) display staining on the interior only, suggesting a functional explanation for its presence. Possible red pigment was observable on eight pipe stem fragments and two pipe bowl fragments, totaling 1.82% of the total pipe assemblage. Four of the fragments (Cat. #11630, Cat. #11629, Cat. #11628 and Cat. #11633) was recovered from external pit feature #382. The remainders were collected from the surface of the site (Cat. #11705, Cat. #11726, Cat. #12361 and Cat. #11729). Black pigment was identified on the exterior of three vessel fragments (Cat. #CS106, Cat. #CS107 and Cat. #CS108; Plate 72). Most archaeologists accept that ochre or haematite was used to create the red colours present in pictographs and on ceramics; however, there is some question as to the identity of the black pigments employed by Aboriginal peoples. Current literature confirms that most red pigments are red ochre (iron (III) oxide and clay) whereas black pigments are manganese (IV) oxide. The pigment decorated pottery from the Mantle site provided the perfect opportunity to explore this research question using new and innovative analytical techniques.

Three body sherds decorated with red and black pigment banding and one disc pipe bowl fragment with a red pigment wash were subject to X-ray fluorescence (XRF) in order to identify the chemical composition of these pigments (Plates 56 and 72). The samples were tested using an Olympus Innov-X Delta Premium X-ray fluorescence unit. The instrument is equipped with an Rh anode X-ray tube and operates at 40 kV. Three beam settings are optimized for accurate measurement of high- medium- and low-Z elements. The unit was calibrated using factory and internal standards and operated in 3-beam mode at 60 seconds each, for a total of 3 minutes per exposure. The fluoresced X-rays are absorbed by a lithium drift detector, and the proprietary software converts counts per second into parts per million concentrations of each of the elements measured.

The red pigment on a ceramic disc pipe bowl Cat. #12388 was identified as an iron-based pigment (Plate 56). The results showed a sizeable Fe peak (~5%), and a lack of other elements that could be

representative of other types of red pigment, for example, Cadmium (Cd) or Mercury (Hg). The sizable Fe peak is a significantly higher value than has been measured for the oxidization of iron in normal clay surfaces (~2%) and therefore proves a red pigment wash coats the surface of this artifact. It is likely that the red wash was applied so as to mimic the Catlinite/red stone disc pipes made in the sixteenth century in the Midwestern United States.

Plate 72: Painted Ceramic Sherds (Cat. #CS106, Cat. #CS107 and Cat. #CS108)

The red pigment on the ceramic sherds Cat. #CS106, Cat. #CS107 and Cat. #CS108 tested was also identified as a similar iron-based pigment to the one used on the disc pipe.

The black pigment on ceramic sherds Cat. #CS106, Cat. #CS107 and Cat. #CS108 was identified as a type of bone black pigment. The results showed a high calcium content (~10-12% for both sherds) which is consistent with charred-bone black pigment chemistry (the other predominant content being carbon and phosphates). There was also a lack of Manganese (<1000ppm), and a low Iron content (~2-3%), both of which, in larger concentrations, could suggest Manganese (Mn) or Iron-oxide based pigments. Continuing work and further discussion of the results of the pigment analysis will be presented in a future article.

### **3.6 Instrumental Neutron Activation Analysis and Petrography Analysis of Mantle Ceramics**

*Andrea Carnevale, Linda Howie and Brandi Lee MacDonald*

The excavation of the Mantle site resulted in the recovery of a significant number of ceramic types referred to regularly as ‘exotic’ types, not commonly found in the ceramic assemblages of Ontario archaeological site. Of particular interest was the presence of a number of Oneida and Onondaga ceramic castellated effigies typically found on archaeological sites in New York State.

Instrumental Neutron Activation Analysis was undertaken to determine if the chemical composition of the Oneida and Onondaga effigies and other ‘exotic’ pottery types from the site were produced from local clay sources, suggestive of Oneida and Onondaga peoples living amongst the Ancestral Huron, or if they were produced elsewhere, constituting an introduced product.

A total of 65 unique vessel sherds, 21 'exotic' types and 44 'local' types, were selected to undergo INAA at MNR at McMaster University. All samples are being analysed for elements with short-lived half-lives with special focus on elements with longer lived radioisotopes. In addition, petrography analysis of each sherd is being conducted to identify clay matrix composition and temper inclusions in the vessel's fabric in order to compare with the results of the INAA and to further understand the question of local vs. foreign manufactured ceramics.

In addition to the ceramic sherds, 25 clay samples from a number of locations across the site and along Stouffville Creek were taken for INAA and petrography analysis. An additional, five samples of a 'grit layer' encountered along the length of Stouffville Creek was also sampled as it may represent a naturally occurring, easily accessible source of temper.

### ***3.6.1 Instrumental Neutron Activation Analysis***

#### ***Sample Preparation***

A total of 65 samples were selected for analysis. Sherds were surface-stripped using a diamond-tipped burr drill bit and samples were clipped and cleaned with deionized water. Samples were ground in an agate mortar and pestle and dried in a low temperature oven overnight. The ceramic powder was weighed to ~1g aliquots in high-purity polyethylene vials.

#### ***Irradiation Protocol***

Two irradiations were performed to collect data on elements that produce short-, medium- and long-lived radioisotopes. Six standard reference materials (SRM) and in-house control samples were run with each batch. SRMs are issued by the National Institute of Standards and Technology (NIST), and include SRM 1632c Coal, SRM 1633b Fly Ash, SRM 688 Basalt, and SRM 278 Obsidian Rock. Samples were first run through a pneumatic tube system and subjected to a 10-second thermal irradiation at a neutron flux of  $3 \times 10^{13} \text{ n cm}^{-2} \text{ s}^{-1}$ . After a 10-minute delay the samples were counted for five minutes on a hyper-pure germanium gamma detector to measure for the elements Al, Ca, Co, Dy, K, Mn, Na, Ti, and V. After 24 hours samples were counted again for 5 minutes to collect data on the elements Eu, K, La, Mn, Na, and Sm. To collect data on elements that produce long-lived isotopes samples were irradiated for two hours at a neutron flux of  $5 \times 10^{13} \text{ n cm}^{-2} \text{ s}^{-1}$ . After 7-10 days samples were counted for 30 minutes each to measure concentrations of As, Ba, Fe, La, Na, Nd, Sb, Sm and Th. Approximately 14-16 days after the long irradiation the samples were counted for another 30 minutes to measure concentrations of Ce, Co, Cr, Cs, Eu, Lu, Sc, and Zn. The raw data were calculated and calibrated using GammaVision™ and PEAK software, and multivariate statistical analyses were performed using SAS JMP software.

#### ***Preliminary Results***

Preliminary results of the elemental analysis suggest that there are possibly two to three geochemically distinct groups of clays within the sample set. Grouping based on elemental concentrations indicates that there is a group with higher concentrations of light rare earth elements that may suggest a different clay source. In addition another sub-set of samples has a significantly higher calcium concentration that could suggest a different clay source or different method of clay preparation. While a larger set of samples is needed to be tested to make more definitive conclusions, these results show promise for further analysis.

### **3.6.2 Preliminary Results of the Petrography Analysis**

In an effort to further investigate the origin of the sherds and the manufacturing process, Linda Howie (2012) conducted a petrographic analysis of 62 of the 65 samples mentioned above.

The analysis identified significant mineralogical distinctions that relate to the place of manufacture, as well as compositional and textural distinctions that reflect differences in paste recipes, in terms of the choice of the raw material ingredients used to make different groups of vessels.

Considerable compositional variation with eleven fabric groups has been distinguished among the 62 vessels. The fabric groups were evaluated for their geological consistency with clay samples that were taken from the site environs. The analysis documented over half (43/62) of the samples as geologically inconsistent with the clay samples taken from around the site. The main geological distinction is the absence of calcitic inclusions (calcites and limestone), which are conspicuous characteristics of the local clay samples and would be expected to appear in the pot samples had local clays been employed in their manufacture.

Some of the groups have sub-variants that exhibit subtle compositional differences that could be significant with respect to teaching children how to make pottery. Within the fabric groups that are geologically consistent with local clays, for example, four of the five groups are represented by only one juvenile vessel. These groups differ in inclusions and abundance and prevalence of segregations, which are related to the compositional properties of the clay component. Together, these may represent novice potters experimenting with mixtures of raw material ingredients to produce pottery successfully. The results suggest that such a scenario might also be expected in instances where potters move into a new area and are unfamiliar with the mechanical performance, drying and firing characteristics of local clays and the effects of adding tempering materials.

The vessels made of non-local fabrics also include compositionally similar regular and 'juvenile' pots although many of the juvenile vessels are untempered. This suggests that these vessels were brought with the families to the site or that task groups continued to acquire non-local clays in sufficient quantities to allow for juvenile and adult pot manufacture together.

Some of the non-local vessels, however, may have come from far-distant sources. One of the distinctive effigy vessel fragments, for example, was found to be geologically inconsistent with the clay samples prospected from the Mantle area, which suggests that this particular vessel, as well as others belonging to the same fabric group, were produced elsewhere and brought to the Mantle site. It is also possible that the clay itself was brought to the site. In this particular group of effigies, ten of the eleven member vessels were classed as 'exotic.' Similarly, eleven of fourteen vessels identified as having been made of local clays were classed as local types. Of the other non-local clay subgroups, there are about as many local as 'exotic' types.

Further analysis is needed to determine the sources or geological origins of the clay components of the non-local fabric groups. Ongoing research is focused on sampling clays from the Spang and Draper sites, thought to have been occupied immediately prior to Mantle. Samples have also been requested from the assemblages of those sites in eastern Ontario and New York State that bear striking stylistic similarities to the 'exotic' vessels including the Cayadutta-Otstungo Incised and Chance Incised effigy vessel fragments.

The results of the INAA and the petrography will be reported in future articles. A final report on Howie's analysis is available from ASI.

## 4.0 FLAKED LITHIC ARTIFACT ANALYSIS

*Deborah Steiss*

### 4.1 Introduction

A total of 6,369 flaked lithic artifacts was recovered from the Stage 3-4 excavations of the site. The assemblage comprised mainly debitage, represented by 6,018 pieces (94.5%) (Table 59). In addition to debitage, 351 formal tools (5.5% of the assemblage) were recovered (Appendix J – Table 1). A complete catalogue of all flaked lithic artifacts from the site is presented in Appendices I and J.

**Table 59: Lithic Distribution**

<b>Artifact Class</b>	<b>Quantity</b>	<b>Percent</b>
<b>Flaked Stone Formal Tools</b>		
Scraper	31	0.5
Drill – complete/fragments	8	0.1
Graver	20	0.3
Projectile Point – complete/fragments	112	1.8
Biface – complete/fragments	164	2.6
Preform	1	0.02
Wedge	15	0.2
<b>Flaked Stone Debitage</b>		
Core	41	0.6
Bipolar Flakes	15	0.2
Edge Removal Flakes	11	0.1
Primary Reduction Flake	2	0.03
Primary Thinning Flake	273	4.3
Secondary Knapping Flake	2,734	42.9
Secondary Retouch Flake	556	8.7
Shatter	2,373	37.3
Miscellaneous Chunks/Cobble	2	0.03
<b>Total</b>	<b>6,369</b>	<b>100%</b>

Evidence of thermal alteration, in the form of “pot-lids” and textural changes such as “krinkling,” was present on approximately 43% of the artifacts (2,742 artifacts), with similar representation on both debitage (43%) and formal tools (37%). Onondaga chert was the predominant raw material used for lithic tool production, comprising 98% of the collection (6,222 artifacts) (Appendix J – Table 2).

Lithic artifacts were derived from controlled surface collection and systematic block excavation of one-metre units during Stage 3 investigations (Appendix J – Table 3-4). Stage 4 artifact yields resulted primarily from block excavation of Midden 1 and associated disturbed deposits (formerly Middens 2 and 3), posts and subsoil features exposed during shovel excavation, and the monitoring of mechanical topsoil stripping (Appendix J – Tables 6-10). Some artifacts were also recovered from the backdirt (Appendix J – Table 5). The block excavations yielded more than 2,000 lithic artifacts (n=2,160) from a total of 115 one-metre units (Appendix J – Tables 6-8).

The excavation of 262 subsurface features and 49 posts contributed an additional 1,357 and 157 artifacts, respectively (Appendix J – Tables 9-10). Included were 56 artifacts recovered from the soil flotation samples taken from features and posts. Forty percent (n=539) of the artifacts recovered from features derived from four features (F55, F709, F927, F986). The balance of 239 features yielded less than ten

artifacts each. Two features (F55, F709), portions of the borrow trench associated with the last occupation and last palisade phase, were essentially midden deposits. Features 927 and 986, yielding 47 and 195 pieces, respectively, were both interior house features (Figures 13 and 14) (Appendix J – Table 10).

Plate 73: Mantle site projectile points

## 4.2 Projectile Points

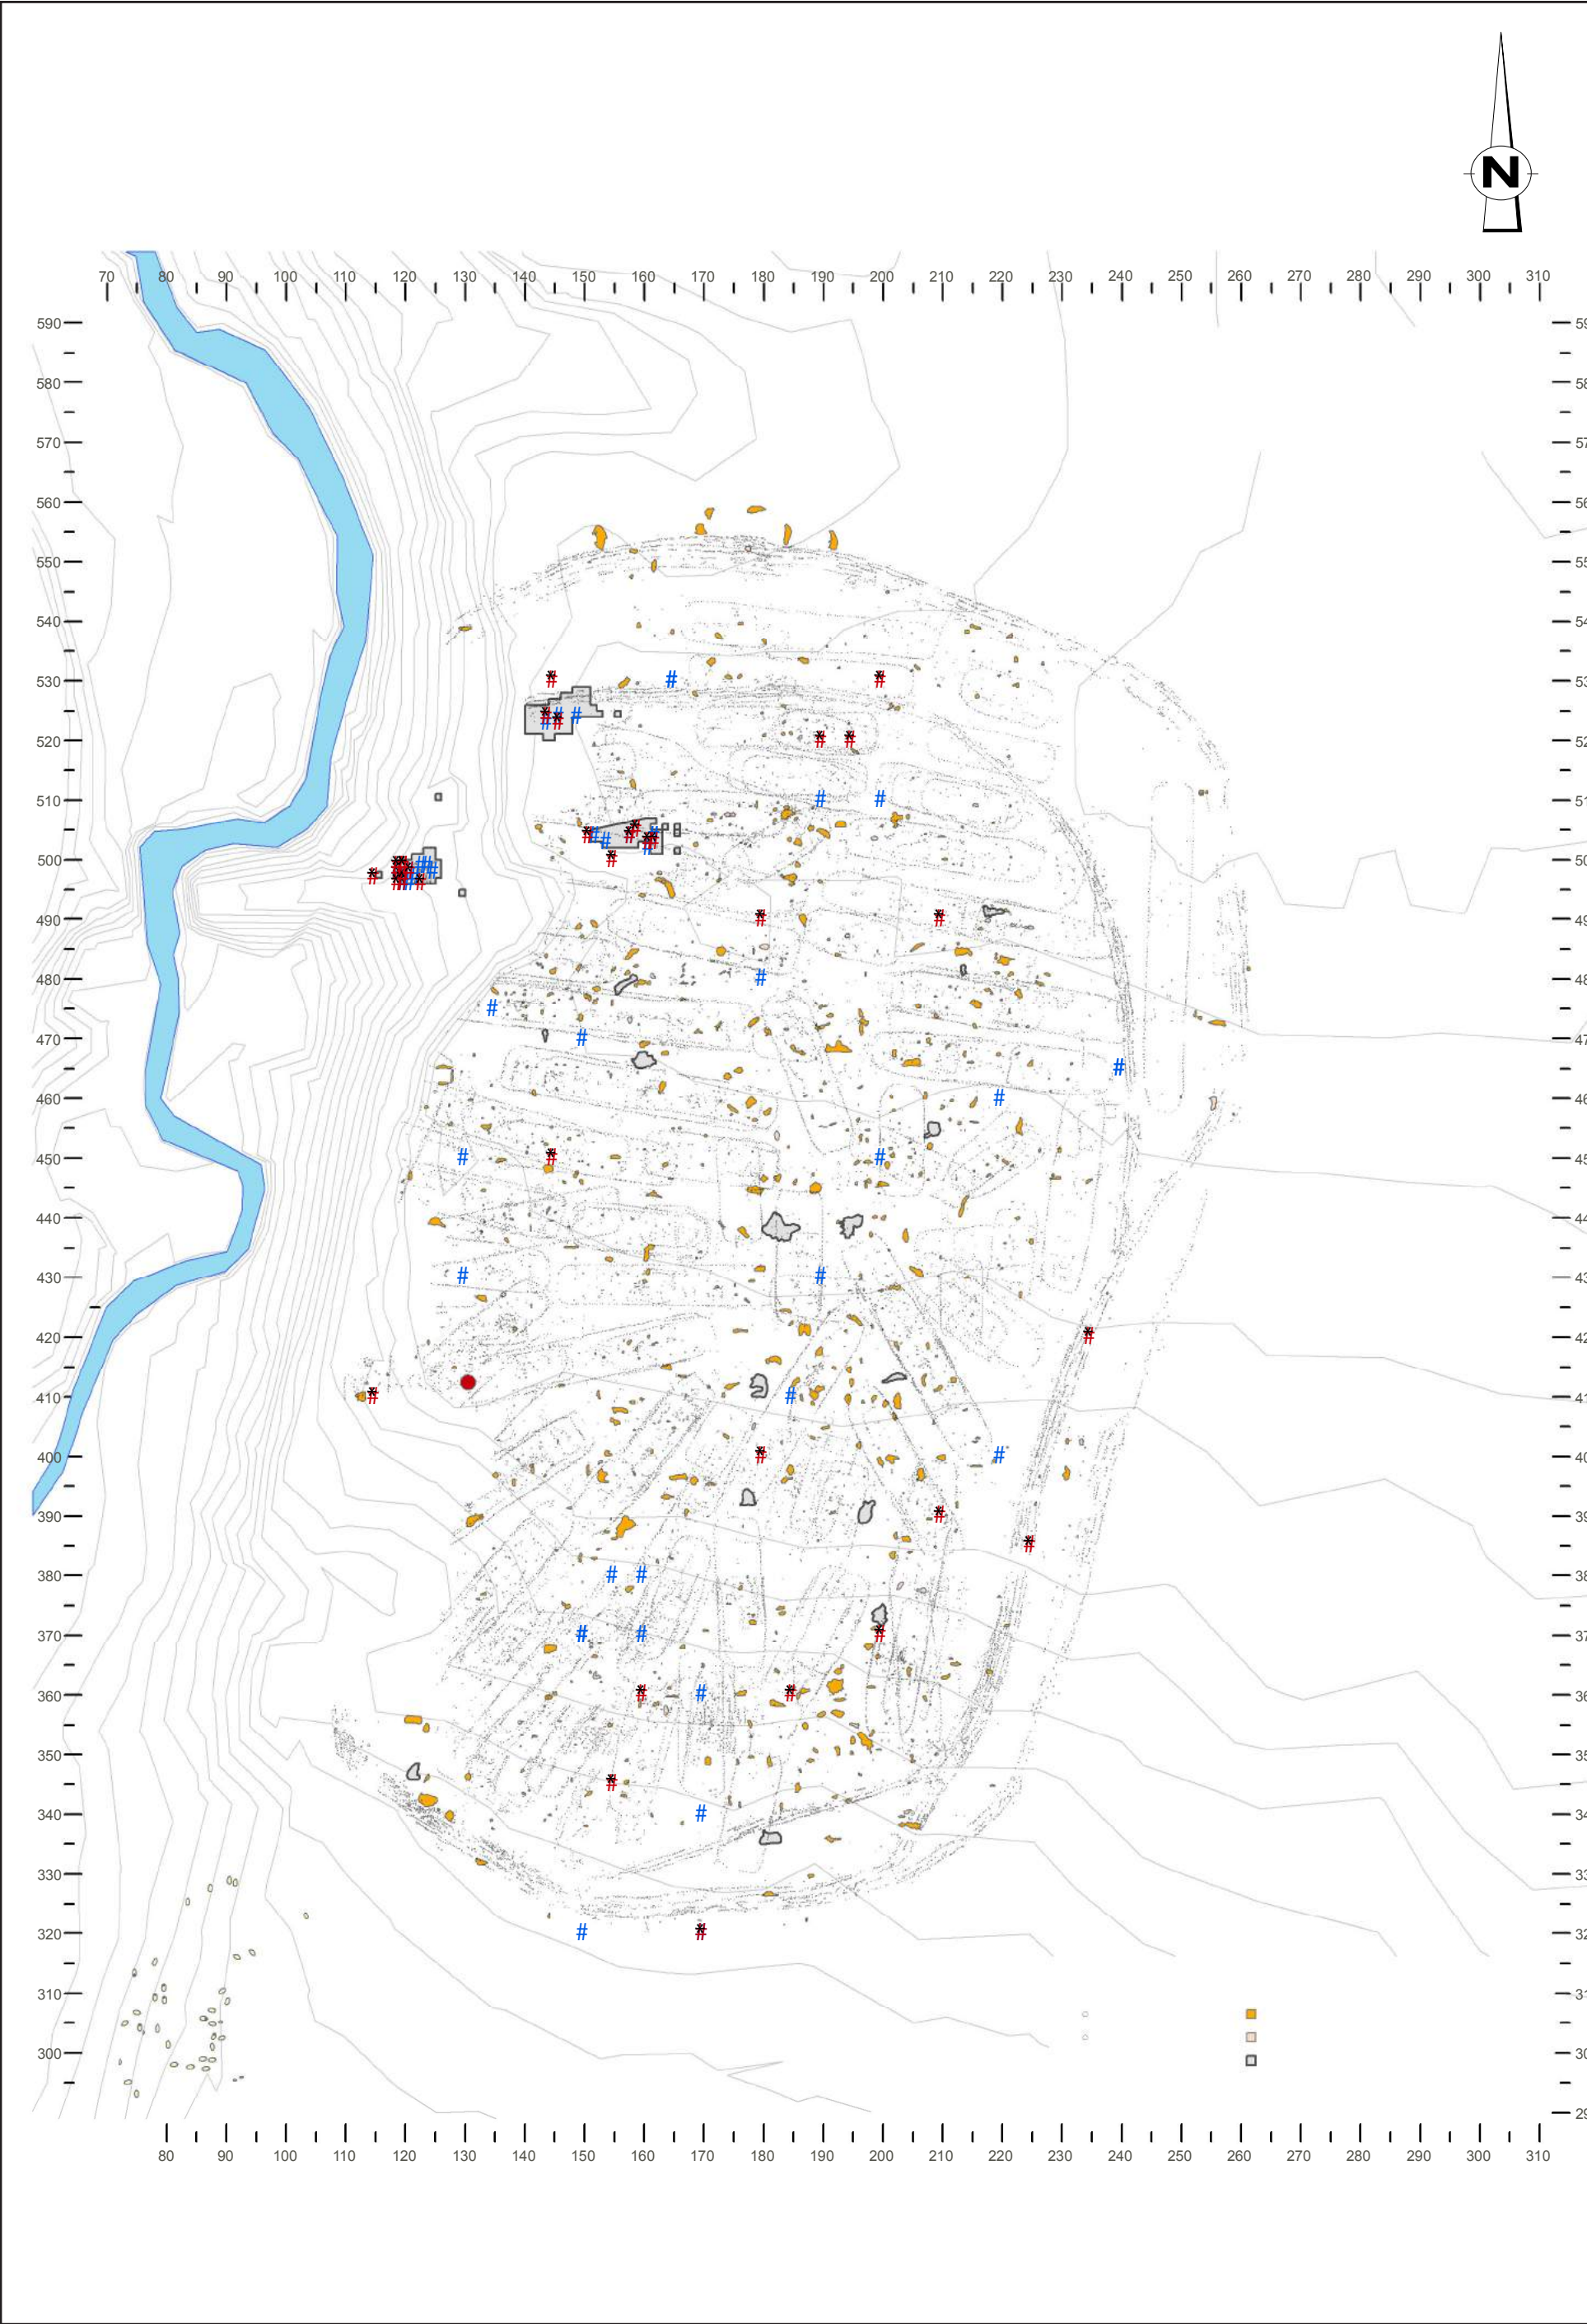

A total of 112 projectile points/ fragments was recovered, including 54 complete projectile points and 58 fragments (Appendix J – Table 11; Plate 73, Figure 52).

The morphology of the complete points was generally consistent with Late Woodland point forms; triangular-shaped with straight or concave bases (Plate 73). Eleven points appeared to be made from flakes with minimal bifacial retouch, while the others were crafted from bifacial preforms. There was a single side-notched point with a square base (Plate 73). The sample of complete Late Woodland points averaged 23 mm long, 17 mm wide, and 6 mm thick, with median measurements of 22, 16, and 5 mm, respectively. Three size categories, by length, were established within the collection: up to 25 mm; 26- 30 mm; and greater than 30 mm. These categories contained 18, 22, and 13 specimens, respectively (Figure 52).

Evidence of thermal alteration is present on only 13% of complete points, one manufactured from Bois Blanc chert and the remainder from Onondaga (Appendix J – Table 11).

<div><div>Archaeological Services Inc. 528 Bathurst St. T 416-966-1069 Toronto, Ontario F 416-966-9723 Canada, M5S 2P9 info@IASI.to/www.iAS±.to</div></div>		<div>BASE: Map Title Map Producer Date, Project or Map No.</div>	<div>050 Meters</div> <div>ASI PROJECT NO.: 05TE08 DATE: March 26 2012</div> <div>DRAWN BY: JF FILE: Mantle_pp</div>
---	--	--	--

Figure 52: Projectile Point Distribution

Fifty-eight fragments of projectile points were also recovered. All were made of Onondaga chert with the exception of two specimens, one identified as Lockport and the other as Bois Blanc chert. Twenty-eight, (50%) of the broken point specimens were basal fragments of probable Late Woodland triangular points, with straight or concave bases. A further 24 fragments (41%) were tip portions only or tips plus midsections. Thirty-six point fragments (62%) displayed evidence of thermal alteration (Appendix J – Table 11).

One complete and one fragmentary triangular point were retouched on the tips, for probable use as graters (Plate 73).

Two partial projectile points and one complete point appeared to be diagnostic of time periods earlier than the Late Woodland. These likely represent earlier hunting people moving through the area. One specimen (Cat. #L127) has a broad, rounded base and very shallow side-notches, resembling a Saugeen point associated with the Middle Woodland period (Plate 73). The second partial specimen (Cat. #L852) has a thick blade and square stem, resembling a Late Archaic Genesee point (Plate 73). The complete specimen (Cat. #L2260) is a shallow, side-notched point, made of Bois Blanc chert, and resembles a Middle Archaic Brewerton point or a possible Middle Woodland one (Plate 73).

The majority of points were recovered from the surface (43%), middens 1 and 3 (28%) and feature deposits, specifically (13%) (Appendix I – Table 11).

Figure 53: Projectile point length, grouped into three size categories.

### 4.3 Bifaces

A total of 164 bifaces and biface fragments was recovered, including 147 biface fragments and 17 complete bifaces (Appendix J – Table 12; Plate 74). The majority of bifaces were manufactured from Onondaga chert (95%), with four specimens made from Kettle Point chert, three from Bois Blanc and a single biface fragment from Fossil Hill chert. Almost half (44.5%) of the biface collection displayed evidence of thermal alteration in the form of pottlidding and/or kinkling. More than half (56%) of bifaces were recovered from midden, post mold or feature contexts. Surface finds accounted for an additional 32% of bifaces (Appendix J – Table 12).

Approximately 90% of bifaces were fragmentary. This included: tip and/or base fragments (n=44); small bifacial edge fragments (n=31); or midsections (n=9). The average dimensions of these fragments were 22.6 mm long, 16.7 mm wide and 5.9 mm thick (Appendix J – Table 12). Larger pieces could be classified as crude or semi-refined versus refined. Eight of the complete bifaces were crude, early stage specimens, half displaying evidence of thermal alteration. There were two complete, refined bifaces including a triangular Kettle Point biface with collateral flaking (Cat. #L1240; Plate 74) and a lanceolate specimen with rounded ends (Cat. #L2250, Plate 74). One small, triangular specimen may have represented a point preform abandoned due to inadequate thinning (Cat. #L2263, Plate 74). Eleven pieces classified as “edge removal” flakes also attest to bifacial reduction activities at the site.

Plate 74: Select bifaces (Cat. # L2250 (top left), Cat. #L2263 (top right) and Cat. #L1240, (bottom))

#### 4.4 Drills

Eight drill fragments were present in the collection, all made from Onondaga chert (Plate 75). Five specimens were recovered from three features: four from the borrow trench and one from Feature 828 (Appendix J – Table 13). The three remaining drill fragments were found in the Midden 1 and associated deposits.

Most drills were fragmentary, with broken bases and/or tips, but one relatively complete drill (Cat. #L725) had a squared base (Plate 75). Most drills were bifacially reduced, but two specimens appeared to have been made on flakes (Plate 75, Cat. #L1699, and Cat. #L2056).

Plate 75: Drills fragments recovered from the Mantle site (cat. #L1699, Cat. #L725, and Cat. #L2056)

#### 4.5 Gravers

Twenty tools identified as gravers were observed, half of which were collected from the surface (n=10), with eight gravers being derived from midden and feature deposits and the remaining two being derived from backdirt (Appendix J – Table 14, Plate 76). Three quarters of the gravers consisted of expedient, retouched graving tips made on flakes and shatter, with one small specimen that had probably been hafted (Cat. #L84). Four gravers were bifacially worked (Cat. #L455, Cat. #L1055, Cat. #L1417, Cat. #L2102). The remaining specimen was unifacially worked with retouched margins (probably for use as a scraper), and had a corner graver projection (Plate 76, Cat. #L854, top row on the left).

Plate 76: Select Gravers, Cat. #L854, Cat. #L2102, Cat. #L1055 (top row).  
Cat. #L455, Cat. #L84, Cat. #L1417 (bottom row).

#### 4.6 Scrapers

Thirty-one scrapers were present, including nine end scrapers (Appendix J – Table 15). All were manufactured from Onondaga chert with the exception of a single, slightly water-worn specimen of Kettle Point chert. The end scrapers were produced on flakes and displayed pronounced distal retouch with no additional dorsal treatment. There was a large end scraper produced on a bifacial blank (Plate 77, Cat. #L2261). One specimen also exhibited bi-lateral denticulation/notching for possible graver use (Plate 77, Cat. #L1472), and another backed end scraper was elliptical in shape and was retouched at both ends (Plate 77, Cat. #L2413).

Other scrapers were predominantly unifacial. Several were intended as multi-purpose tools, such as: combination scrapers/gravers (Cat. #L68, Cat. #L95, Cat. #L1733); combination end/ side scrapers (Cat. #L1572, Cat. #L2145, Cat. #L2366, Cat. #L2409); and a scraper with multiple graver tips as well as a spokeshave edge (Cat. #L407).

Two bifacial scrapers were identified. One is a thin end scraper that tapers proximally for possible hafting (Cat. #L2257), and the other is a biface edge fragment with steep retouch (Cat. #L2367).

Thirteen scrapers were recovered during controlled surface collection, five derived from the backdirt and the remainder originating from midden and feature contexts.

Plate 77: Select Scrapers, (Cat. #L2261, Cat. #L2413 and Cat. #L1472)

#### 4.7 Cores and Wedges

Forty-one cores were identified, including: multi-directional, rotated cores (n=15); bifacial cores (n=4); and bi-polar cores (n=9) (Appendix J – Table 16). The remaining 13 specimens were fragmentary and not identified by reduction technology. All cores were of Onondaga chert and approximately 40% (n=15) specimens appeared to be “exhausted” or spent, indicating heavy use and conservation of lithic raw material.

Other than the presence of bipolar cores at the site, bipolar reduction technology is also evidenced by the recovery of bipolar flakes (n=15) and “wedges” or “pieces esquilles (n=15), characterized by a roughly square shape and battering at opposing ends (Appendix J – Table 17). All were of Onondaga chert with the exception of a single specimen identified as Upper Mercer chert (Cat. #L670), which also had worked edges converging to a probable graver tip.

Similarly to other tools, approximately half of the cores were recovered during controlled surface collection and the remainder was derived from midden and feature excavation.

## 4.8 Discussion

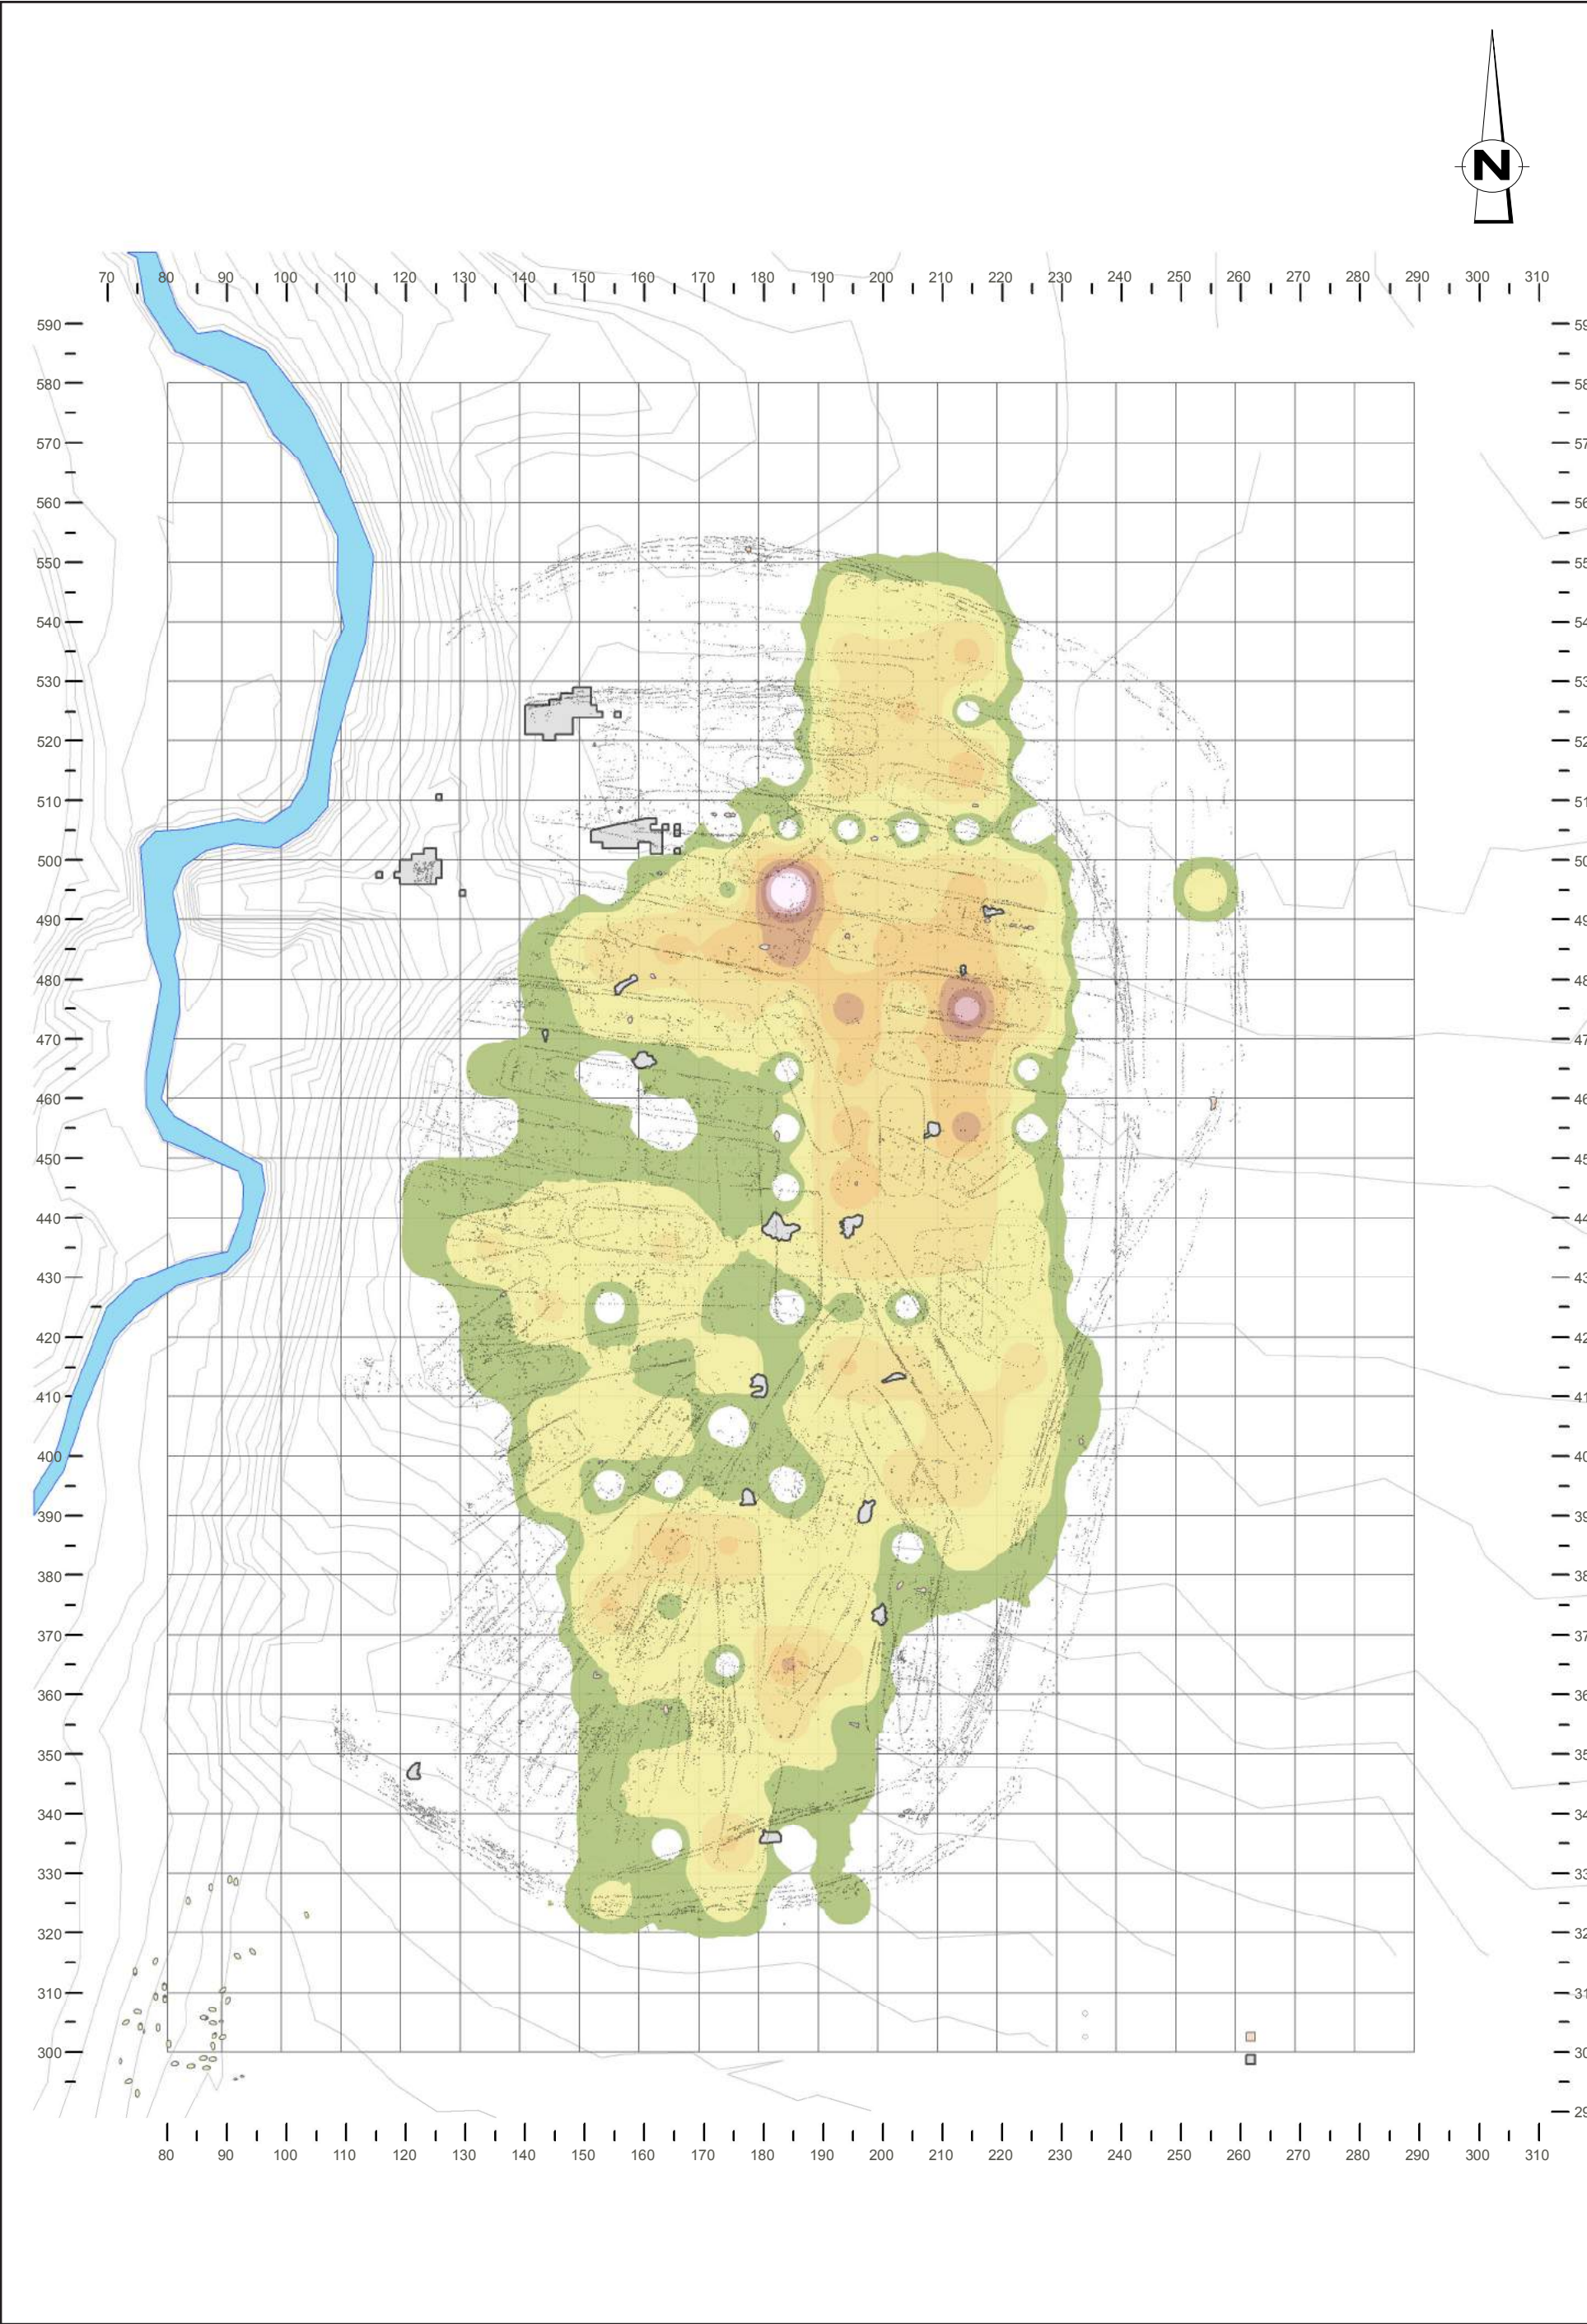

In order to understand behavioural patterns relating to the production and use of flaked lithic tools at Mantle, the distribution of lithic artifacts was plotted across the site using ArcView GIS 10. Figure 52 shows the distribution of projectile points and point fragments across the site. Most of the projectile points and point fragments cluster in the midden deposits in the northwest corner of the site. There is no other obvious pattern to the distribution of points across the rest of the site.

The pattern of the distribution of debitage across the site is noticeably different (Figure 47). Concentrations of debitage occur in the north-central portion of the site, most notably in and around Houses 25 and 27, and within the east end of House 15. While House 25 and House 27 were occupied during the early phase of settlement at the site, House 15 was probably in use for much of the duration of the occupation of the site and has been identified as a possible chief's house. It is possible that the areas of concentration in and around Houses 25 and 27 may have been outdoor activity areas at some point during the occupation of the site, but given the long tenure of occupation in House 15, it is likely that the processing of flaked lithic artifacts was occurring within the house itself. An additional area of concentration is observable to the south of House 27, and within what may have been the main plaza area of the site in the early phase of occupation. It is possible that this concentration of lithic artifacts in this area represents an activity area within the plaza.

Slightly more than half of the artifacts excavated from post fills displayed thermal alteration (n=82). Approximately 48 % of artifacts from Midden 1 displayed thermal alteration, and midden deposits together contained roughly 34% of thermally altered material present on the site (n=942). Feature excavation contributed an additional 569 (42%) thermally altered pieces and, together with the midden and post totals, comprised 58% of thermally altered materials deriving from these contexts. Artifacts recovered from contexts excluding middens, post molds or features, including both one metre square excavations and surface finds, contributed a lower thermal alteration percentage (37%). This may demonstrate the predilection for removing lithic debris from around hearths and other areas into convenient refuse areas whenever possible (for example, into middens, the borrow trench or refuse-filled depressions). This appears to be the case at Mantle, with observable concentrations of thermally altered debitage along the western edge of the site, corresponding with the slope midden in the northwest portion of the site (Figure 48).

## 5.0 GROUND STONE ARTIFACT ANALYSIS

*Martin S. Cooper*

### 5.1 Introduction

A total of 488 ground stone artifacts was recovered from the site. This included 375 celts and celt fragments, 25 stone beads and stone bead pre-forms, 33 hammers, 13 stone pendants, eight pipes, five whetstones, two bannerstones and single examples of a metate and a pecking tool. Sixteen ground stone artifacts were classified as miscellaneous (Table 60). Appendix K provides descriptive attributes for these artifacts.

**Table 60: Ground Stone Artifact Class Totals**

Artifact Class	Frequency	Percent
Celts	375	76.8
Hammers	33	6.8
Whetstones	5	1.0
Beads	25	5.1
Pendants	13	2.7
Metate	1	0.2
Cobble/Pecking tool	1	0.2
Bannerstone	2	0.4
Pipes	8	1.6
Fossils	9	1.8
Miscellaneous Ground Stone	16	3.3
<b>Total</b>	<b>488</b>	<b>100.0%</b>

### 5.2 Celts

Celts are a category of ground stone woodworking tools that include axes, adzes and chisels. If the function of the tool cannot be determined because of its incomplete nature, it is placed in the general category of celt. Of the 375 (77%) celt and celt fragments, 41 were complete enough to determine that they likely functioned as axes. While axes have a symmetrical bit, adzes have an asymmetric bit. Twelve such adzes were recovered from Mantle. Twenty-four celts have been classed as chisels or fine woodworking tools based on their small size. Two celt fragments were modified along one edge after they had been broken, and these items are referred to as beveled tools.

The function of the remaining 296 celt portions and fragments could not be identified, largely because they were incomplete. Of these 278, sixteen celts were three quarters complete, twelve were half complete, and four were only one quarter complete (Appendix K). One hundred and seventy-seven midsection fragments, 104 bit fragments and 22 poll fragments were also recovered. A total of 30 celt bit fragments was derived from the corner of the bit, suggesting that they may have been detached during use. These include seven axe, one adze, one chisel and 17 celt (specific function unknown) bit corner portions.

In terms of material, chloride schist was the predominant stone used for the manufacture of celts, and it accounted for approximately 97.1% of the celt assemblage (Appendix K). Chloride schist is an ideal material for adzes, axes and chisels as it is hard, fine grained and can be honed to a keen edge. Chloride schist is available in close proximity to the Mantle village. It occurs in the till and is available as large cobbles in the adjacent creek bed. Evidence of unmodified chloride schist cobbles and the presence of celt preforms indicate that these tools were being manufactured at the Mantle site. Other materials used in celt manufacture include two items made of amphibolites and single examples of diorite, biotite, slate, gneiss, limestone and four celts made of an unknown material.

A number of celts and celt fragments exhibit thermal alteration. Seventy-one celts and celt fragments (representing approximately 20% of the celt assemblage) have been thermally altered (Appendix K). Burning results in noticeable oxidization and discoloration of the schist, and in severe burning the fragments are fire cracked, as attested by their angular nature. Thermal alteration has not been observed in other late Iroquoian assemblages, and may result from a significant fire within the village or intentional deposition of broken celts into fire. Twenty-four celts and celt fragments were found in posts, suggesting that they were placed there intentionally, possibly to stabilize the post. Other stone artifact types were also found in posts, including four cobble hammers, a stone pipe, a soapstone bead and a piece of miscellaneous ground stone.

### Axes

Forty-one celts were classed as axes based on their symmetrical bit and relatively large size (Appendix K; Plate 78). All of the axes were made of chloride schist, except for a single example made of diorite (Cat. #G385) and a single example made from amphibolites (Cat. #G425). Axes were likely used for felling trees and chopping firewood, and were the primary tools for clearing forests to open up areas for the construction of villages and to clear fields for planting. They were also used as wedges for splitting wood into planks. Axes that had been used for splitting can be identified by battering at the poll end and chipping and battering on the bit.

Plate 78: Select Axes (Cat. #G35, Cat. #G376 and Cat. #G450, top row; Cat. #G373 and Ca. #G40)

Seven complete axes were recovered. Length ranges from 70 to 106 mm, with a mean length of 95 mm. Width ranges from 37 to 51 mm, with a mean width of 44 mm. Thickness ranges from 13.5 mm to 35 mm with a mean thickness of 20 mm. Five axes were thermally altered.

### Adzes

Twelve adzes were identified in the ground stone assemblage based on their asymmetrical bit and relatively flat ventral side (Plate 79). Two of these adzes was thermally altered (Cat. #G198 and Cat. #G449). Adzes functioned for gouging and planing wood and were likely used for the manufacture of dugout canoes.

Plate 79: Select Adzes (Cat. #G149, Cat. #G198 and Cat. #G233)

Two complete adzes were recovered (Cat. #G239 and Cat. #G269). Length ranges from 104 to 144 mm, with a mean length of 125 mm. Width ranges from 47 to 56 mm, with a mean width of 51 mm. Thickness ranges from 20 to 35 mm, with a mean thickness of 29 mm (Appendix K).

### Chisels

Twenty-four celts were classed as chisels based on their small size. Chisels were used for fine woodworking, planing and carving. All but two of the chisels (Cat. # G236 and Cat.# G480) have a symmetrical bit, and all but two (Cat. #G77 and Cat. #G282) were made of chloride schist. These two exceptions were made from unidentified materials (Appendix K).

There were 11 complete chisels. Chisel length was variable, ranging from 43 to 84 mm, with a mean length of 70 mm. Chisel width ranged from 19 to 38 mm, with an average width of 28 mm. Chisel

thickness ranged from 5 to 19 mm, with a mean width of 12 mm. One chisel showed possible thermal alteration (Cat. #G171).

It appears that the majority of the chisels were hafted onto wood or bone handles. This assumption is primarily based on the observation that there is a high degree of use wear and polish near the working end, while there is very little wear at the proximal or poll end of the tool. Hafting can explain this difference in that the proximal end would not have been exposed or used.

### 5.3 Hammers

Hammers consist of ovoid pebbles or cobbles with at least one working facet that exhibits pecking and/or grinding. These tools were likely brought to the site to be used in chert tool manufacture, and would have been used in the initial reduction stages of tool manufacture.

A total of 33 hammers, including 30 complete and three incomplete items, was recovered (Appendix K). In terms of material, 17 hammers were made of granite, eight were made of limestone, three were made of gneiss, three were made of diorite, one was made of chlorite schist and one was made of sandstone. Four hammers from the site were recovered from posts moulds (Cat. #G261, Cat. #G348, Cat. #G444 and Cat. #G445) (Plate 80). These materials would have been readily available in riverine, lacustrine and glacial deposits in close proximity to the Mantle village.

Plate 80: Select Hammers (Cat. #G261, Cat. #G348 and Cat. #G445)

Pitted hammers, sometimes referred to as pitted or bi-pitted anvil stones, are cobbles that possess a centrally placed depression on one or both surfaces. These depressions, which range from well developed depressions to simple surface roughening, were used to provide a secure grip. Twenty five (76%) hammers possessed either single (n=15) or bilateral (n=10) grip pitting, while the remaining 7 had no grip pitting.

Hammers often have one or more hammer facets represented by pitting or pecking on the lateral margins. Hammer facets were observable on 32 of the Mantle hammers. Fourteen hammers had multiple hammer facets, six hammers had two facets, and another 12 had single facets.

Hammers can be classified into two groups based on their size: pebble hammers and cobble hammers. There were six pebble hammers in the assemblage, which ranged in length from 54 to 64 mm, with a mean length of 58 mm. Width ranged between 26 and 62 mm, with a mean width of 47 mm, and thickness ranged between 15 and 40 mm, with a mean thickness of 27 mm.

Twenty-seven cobble hammers were recovered. These ranged in length from 73 to 120 mm, with a mean length of 93 mm. Their width ranged between 52 and 111 mm, with a mean width of 84 mm, and their thickness ranged between 30 and 49 mm with a mean thickness of 41 mm.

#### **5.4 Whetstones**

Five whetstones or abraders, used for sharpening stone tools, were recovered from the Mantle site (Appendix K). One is a whetstone fragment made on a small water-worn limestone cobble with smoothing on both faces (Cat. #G170). The second is a sandstone whetstone fragment with smoothing on one surface (Cat. #G183). The third and fourth (Cat. #G93) are two pieces that mend together to form a rectanguloid shaped whetstone. It is made from an unidentified material that may be Arkansas stone. This whetstone may also relate to the Euro-Canadian occupation on the property. The final whetstone (Cat. #G155) is small and has concave surfaces on opposing faces that were used for sharpening tools. This item measures 82 mm in length, 50 mm in width and 14 mm in thickness.

#### **5.5 Stone Beads**

A total of 25 stone beads, bead preforms and stone discs was recovered, which represents 5.1% of the total ground stone assemblage (Appendix K; Plate 81). These include 16 finished beads, three bead preforms, and six discs with no evidence of perforation. Since these beads are in various stages of completion, they provide information on the complete manufacturing process beginning with the raw material and ending with the finished bead. Bead production begins with the rough shaping of a disc, which is then smoothed on the lateral margins. Perforation is accomplished by drilling centrally-placed holes on both sides of the bead. This bidirectional drilling results in less breakage. Once the perforation is completed, the bead is further shaped and polished as desired.

The 16 finished beads consist of 12 discoidal black shale beads; two steatite beads (including one round bead of green steatite and one discoidal bead made of black steatite); and two beads made of sandstone. One of the shale beads appears to be grey, but this may be due to oxidation related to thermal alteration. Perforations in all but two beads were bidirectional, indicating that the hole was made by drilling from both faces. This is also attested to by one of the unfinished items described below that had two incomplete perforations on both sides. All but one of the discoidal beads had centrally placed perforations. The exception has a slightly offset perforation.

Discoidal shale beads ranged from 4.5 to 19 mm in diameter, with a mean diameter of 12.7 mm. Bead thickness ranged from two to eight mm with a mean thickness of 3.5 mm.

Bead preforms were identified based on the presence of one or more incipient perforations, indicating that they were lost or discarded prior to finishing. Two preforms, both discoidal and made of black shale, were recovered. One of these had the beginning of two centrally placed conical perforations on each face, while the other had only one incipient centrally placed perforation. These confirm that shale bead manufacturing was taking place at the Mantle village.

The five stone discs are similar in size to the discoidal shale beads, but exhibit no evidence of perforation. While they may be blanks for future bead manufacture, they may also have functioned as gaming pieces. Three of the discs appeared finished and exhibited surface polish, suggesting that they may have been used for purposes other than bead preforms.

One of the stone beads (Cat. #G151) was remarkable due to material and relatively large size. This bead was made of pink sandstone measuring 24 mm in diameter and 13 mm in thickness. It had a bidirectional perforation and a series of incised lines encircling the outer edge of the bead.

Plate 81: Select beads

The complete green steatite bead (Cat. #G336) is round in shape measuring 9 mm in diameter and 8 mm in thickness. It has high surface polish.

A large pink granite disc (Cat. #G202) is possibly a bead preform or a gaming piece. It has been smoothed over its entire surface with small centrally placed holes on both faces. These holes may be the start of bidirectional perforation.

## 5.6 Stone Pendants

A total of 13 stone pendants was recovered, including three manufactured pendants and ten pebbles with natural perforations (Appendix K; Plate 82). The first of the manufactured pendants is a relatively thin unfinished black shale pebble pendant (Cat. #G67). It has incipient perforations on both faces and measures 21 mm in length, 17 mm in width, and four mm in thickness.

Plate 82: Select Pendants

The second item (Cat. #G271) is a pebble pendant made of orange-red slate. It has two notches on one lateral margin and a bidirectional perforation, and it exhibits surface polish, possibly from use wear. It is 27 mm in width and 7 mm in thickness, but the bottom portion of the pendant has been broken off.

The third is small black shale ovoid pebble pendant (Cat.# G298) with a centrally placed unidirectional perforation. The obverse side of the pendant appears to be exfoliated. It measures 19 mm in length, 12 mm in width and three mm in thickness.

The remaining ten pebble pendants have natural, non man-made, perforations. These items may have simply been present at the site, or they may have been used as ornaments. Three of these appear to have surface polish related to use wear, suggesting the latter. Six of the natural pendants are limestone, two are sandstone, and a single item is made of an unidentified material.

## **5.7 Metate (Grinding Tool)**

One fragment of a large red sandstone metate (Cat. #G31) was recovered. A small portion of a depressed grinding surface is present on one face (Appendix K).

This item was probably used to grind maize and other plant material. Given the importance of horticulture to Iroquoian communities, it is not surprising that large grinding stones are encountered, although in low frequencies, on Iroquoian village sites.

## **5.8 Cobble (Pecking Tool)**

A single pecking tool (Cat. #G473), likely used in stone tool manufacture, was recovered. It is a pointed cylindrical cobble measuring 89 mm in length, 40 mm in width and 39 mm in thickness. It has been modified at the pointed or working end (Appendix K).

## **5.9 Bannerstone**

A single, broken bannerstone (Cat. #G1) and a small bannerstone fragment (Cat. #405) was recovered from the Mantle site (Plate 83). The broken bannerstone appears to be one half of a winged bannerstone made of Huronia banded slate that was broken at the central perforation (Appendix K). After it had broken, there was an attempt to perforate the bannerstone at the top and bottom near the fractured central perforation. These holes may have been intended for suspension after the bannerstone broke, or they may have been incipient mending holes. The surface of the bannerstone has numerous parallel scratches and striations perpendicular to its long axis.

Bannerstones are believed to have functioned as counter weights for atlatls or throwing boards and generally date to between 7,000 and 3,000 B.P. Given that this bannerstone dates to a much earlier time period, it would appear that it was picked up by a Mantle site villager and was kept as a curio. The attempted perforations after breakage appear to represent an effort to modify the broken bannerstone for use as a pendant.

Plate 83: Bannerstone (Cat. #G1)

## 5.10 Pipes

Eight stone smoking pipes represented by bowls and bowl fragments were recovered from Mantle. These include two made of shale, five made of limestone, and two made of steatite (Appendix K).

One of these pipes is half of an unfinished black shale vasiform pipe bowl (Cat. #G142) that may have been broken while being manufactured. It has an unfinished stem perforation on one lateral margin and an unfinished suspension hole at the base. The bowl itself has been roughed out, and it is possible that the pipe split during the process of hollowing out the bowl. It may have been discarded at this point, but a hole may also have been drilled into the missing side of the bowl as is evidenced by the base of a perforation. A series of horizontal incised lines are located on the edges of the pipe bowl, four on the side with the pipe stem bore (two above and two below the bore) and five on the opposing side.

A second black shale pipe bowl (Cat. #G335) is represented by two mended portions. Decoration on upper area of bowl consists of oblique incised lines above two incised horizontals.

A small complete limestone pipe bowl (Cat. #G244) has finished stem and bowl perforations. It is made from a chalky limestone ovoid pebble. It exhibits pecking and possibly pigment on its outer surface. There is incomplete horizontal incising near top of bowl.

A highly fossiliferous limestone pipe bowl section (Cat. #G259) appears to have been broken above the stem perforation, which seems conical. The bowl is outflaring with slight collaring at the top of the bowl rim. Fossils are found throughout the piece, which has a distinctive white colour.

Two limestone pipe bowl rim fragments (Cat. #G146 and Cat. #G245) are present in the assemblage. One fragment is thermally altered (Cat. #G146).

A small fragment of a steatite pipe bowl rim (Cat. #G108) was also recovered. It has decoration consisting of vertical incising and the remnants of deep vertical grooves above.

Plate 84: Vasiform pipe bowl (Cat. #G483)

A complete vasiform pipe bowl was also recovered (Cat. #G483; Plate 84). It is made of light brown steatite with a round stem perforation, below which is a suspension perforation that extends on an angle through the bottom of the bowl. While somewhat obscured by the adherence of lime mortar resulting from the construction of a mill structure wall through Midden 1 from where the piece originated, a symmetrical polish pattern is present on one third of the pipe in the region of the stem attachment and along the ridge of the bowl. This may have resulted from a covering of the back of the bowl where it would have been held and polishing only that portion that was exposed. The bowl is rectangular in cross

section with rounded corners, and the lip of the bowl is flat with decoration on a short collar consisting of four single horizontal incisions and short vertical incisions at the corners.

### **5.11 Fossils**

Nine fossils were recovered from Mantle. These include seven crinoid fossils, a single cephalopod fossil and a portion of a large unidentified fossil. None of the fossils were culturally modified, although all but one (Cat. #G328) were found in features and middens. This may suggest that, although the fossils may have found their way fortuitously into cultural deposits, they may also have been collected as curios.

### **5.12 Miscellaneous Ground Stone Items**

The miscellaneous ground stone category includes fifteen ground stone artifacts that could not be classified by artifact type or function. Of particular interest are a small flat ovoid pebble with lateral notching that appears to be a netsinker but is much smaller and a rough stone spall flake with surface polish and a four sided “conical” or pyramidal shaped piece of black shale with a blunted apex. This latter item exhibits scarification on its surface consisting of parallel scratching and its base has two parallel grooves. It is suggestive of a stone effigy resembling the head of a dog or wolf but may be an esoteric object.

Other items of note included a trianguloid shaped piece of tabular chloride schist with polish on the edge, a possible bead preform made of steatite that appears to have been smoothed on one face, and a possible limestone bead portion that may be natural. A polished limestone fragment possibly derived from pipe bowl, a small sandstone disc (possibly a bead perform), and a black shale disc (another possible bead perform) were also encountered.

### **5.13 Discussion**

Ground stone artifacts at the Mantle site were recovered throughout the village, although there is a notable absence of these artifacts from the central area of the site (Figure 56). There appear to be concentrations of ground stone artifacts in the north (just within and outside the late palisade) and northeast portions of the site (in and around House 25). There is also a concentration of objects just outside the late southern palisade. The north and south concentrations of ground stone outside the late palisade correspond with the location of the trench midden (see Figure 5), although it is also possible that these concentrations represent activity areas associated with the early occupation of the site. The northernmost ground stone concentration within the palisade and the concentration associated with House 25 almost certainly represent activity areas, and the House 25 concentration overlaps with a concentration of flaked lithic debitage in this same house area (see Figure 54). These latter ground stone activity areas may have been utilized primarily during the late occupation of the site.

Thermally altered ground stone artifacts are largely distributed evenly across the site, although there is some clustering in the northwest portion of the site (Figure 57). Most thermally altered ground stone artifacts therefore were probably discarded in hearth areas, where they were incidentally burned before being discarded.

## 6.0 METAL ARTIFACT ANALYSIS

*Andrea Carnevale*

### 6.1 Introduction

A total of five metal artifacts was recovered from the site. This includes three copper beads, one copper sheet scrap (inlaid in a ceramic pipe) and one bevelled iron tool (Table 61). The metal artifact assemblage can be divided into two subgroups: Precontact Copper Artifacts and European Copper and Iron Goods. The first group are artifacts manufactured by Aboriginal peoples from local copper ore sources while the second group are European manufactured items brought in during the Early Contact period (ca. A.D. 1480/1500-1614) that were modified by Aboriginal peoples into their own ornamental or utilitarian tool types and forms.

**Table 61: Mantle site (AlGt-334) Copper and Iron Artifact Catalogue**

Cat. #	Provenience	Area	Artifact Type	Material	Length (mm)	Width (mm)	Thickness (mm)	Comments
M1	445-215	PM1	tube	Copper	26.7	5.1	0.5	European Copper
M2	497-115	Midden 1	bead	Copper	10.1	4.9	0.45	European Copper
M3	530-180	F709	bead	Copper	8.5	10.3	3.7	Native Copper
M4	499-123	Midden 1	scrap	Copper	4.9	3.2	0.6	Native Copper, inlay in ceramic pipe
M5	445-200	House 28 F1464	Beveled tool	Iron	72.6	25.2	9.0	Heavily corroded

### 6.2 Copper Artifacts

#### 6.2.1 Visual Examination and Technological Practices

In order to explore whether the copper artifacts were of Native or European manufacture, a visual examination of the manufacturing techniques and each artifact's form was undertaken. Following the criteria for technological practices laid out in Dr. Lisa Anselmi's dissertation (2004), each artifact was examined under low-power magnification (8-30x) for manufacturing techniques used to craft each piece. Determination of working techniques was also based on experimental research by Zacharias (1983 and 1989) and Martin (1999). A simple scratch test was performed to remove the patina from a small sample area (1 x 2 mm) on each artifact to allow for a visual determination of the material. Copper yields a red color when scratched, while the most common copper-alloy imported into the New World, brass, yields a yellow colour.

A single long, thin tubular bead (Cat. #M1; Plate 85) measuring 26.7 millimetres in length, 5.1 millimetres in width and 0.5 millimetres in thickness was recovered from a post mould. The scratch test revealed a red colour. This tubular bead was fashioned from a rectangular blank, scored and removed from a source material and rolled into a tubular form, likely around a wooden stick used as a mandrel. The overlapped seam is not straight but skewed and has a slightly scalloped edge. There is no evidence of

grinding along the seam or either end of the bead. No evidence of European manufacturing techniques was identified on this artifact.

Plate 85: Tubular bead (Cat. #M1)

A short, thin tubular bead (Cat. #M2; Plate 86) measuring 10.1 millimetres in length, 4.9 millimetres in width and 0.45 millimetres in thickness was recovered from a test unit in Midden 1. The scratch test revealed a red colour. This tubular bead was fashioned from a rectangular blank, removed from a source material and rolled or bent into a tubular form, likely around a wooden stick used as a mandrel. Several indentations are present on the surface of the bead that may represent hammering/flattening. The overlapped seam is not straight but skewed and has a slightly scalloped edge. There is no evidence of grinding along the seam; however, grinding is present on both ends of the bead. No evidence of European manufacturing techniques was identified on this artifact.

Plate 86: Tubular bead  
(Cat. #M2)

A short, thick rolled bead (Cat. #M3; Plate 87) with rounded ends measures 8.5 millimetres in length, 10.3 millimetres in width and 3.7 millimetres in thickness was recovered from the borrow trench feature. The scratch test revealed a red colour. This bead is multilayered, resulting from the overlapping of material as the blank was rolled. Both ends of the bead have been ground. No evidence of European manufacturing techniques was identified on this artifact. According to Anselmi (2004), beads of this form have been recovered in higher numbers from Seneca sites such as the Cameron, Tram, Warren and the Factory Hollow sites. Aside from a single example recovered from the Huron-Wendat Auger site, no other examples have been recovered from Huron-Wendat contexts; therefore it may represent a traded item (Anselmi 2004).

Plate 87: Rolled bead (Cat. #M3)

A thin, rectangular sheet scrap (Cat. #M4; Plate 88) measuring 4.9 millimetres in length, 3.2 millimetres in width and 0.6 millimetres in thickness was bent into a chevron form and pressed/inlayed in a punctuate of a ceramic pipe (Cat. #12387; Plate 49 (pipe)). The scratch tests revealed a red colour. The short edges of the scrap have been bent as evidenced by the upturned portion/lipping on both edges. No evidence of European manufacturing techniques was identified on this artifact.

Plate 88: Scrap (Cat. #M4)

### 6.2.2 Surface Analysis of Copper Artifacts using X-ray fluorescence (XRF)

***Andrea Carnevale and Brandi Lee MacDonald***

The beads and scrap were subject to X-ray fluorescence in order to confirm the raw material as copper and identify whether the copper was Native or European in origin. The artifacts were tested using an Olympus Innov-X Delta Premium X-ray fluorescence unit. The instrument is equipped with an Rh anode X-ray tube and operates at 40 kV. Three beam settings are optimized for accurate measurement of high-medium- and low-Z elements. The unit was calibrated using factory and internal standards and operated in 3-beam mode at 60 seconds each, for a total of three minutes per exposure. The fluoresced X-rays are absorbed by a lithium drift detector, and the proprietary software converts counts per second into parts per million concentrations of each element measured.

The results of the analysis were compared to a database of over 1,600 copper samples of both Native and European origin (Hancock 2012). Elements that are diagnostic for the differentiation of European and Native coppers include Gold (Au), Silver (Ag), Arsenic (As), and Antimony (Sb) (Fox, Hancock, Pavlish 1995, Ehrhardt 2005). Two of the samples (Cat. #M1 and Cat. #M2) fall within the range of elemental concentrations expected for European copper (high silver and arsenic content), while the other two (Cat. #M3 and Cat. #M4) fall within the range for Native copper (Figure 58).

The first bi-plot shows Sb / Ag; the second shows As / Ag. The differences are distinct (Figure 58).

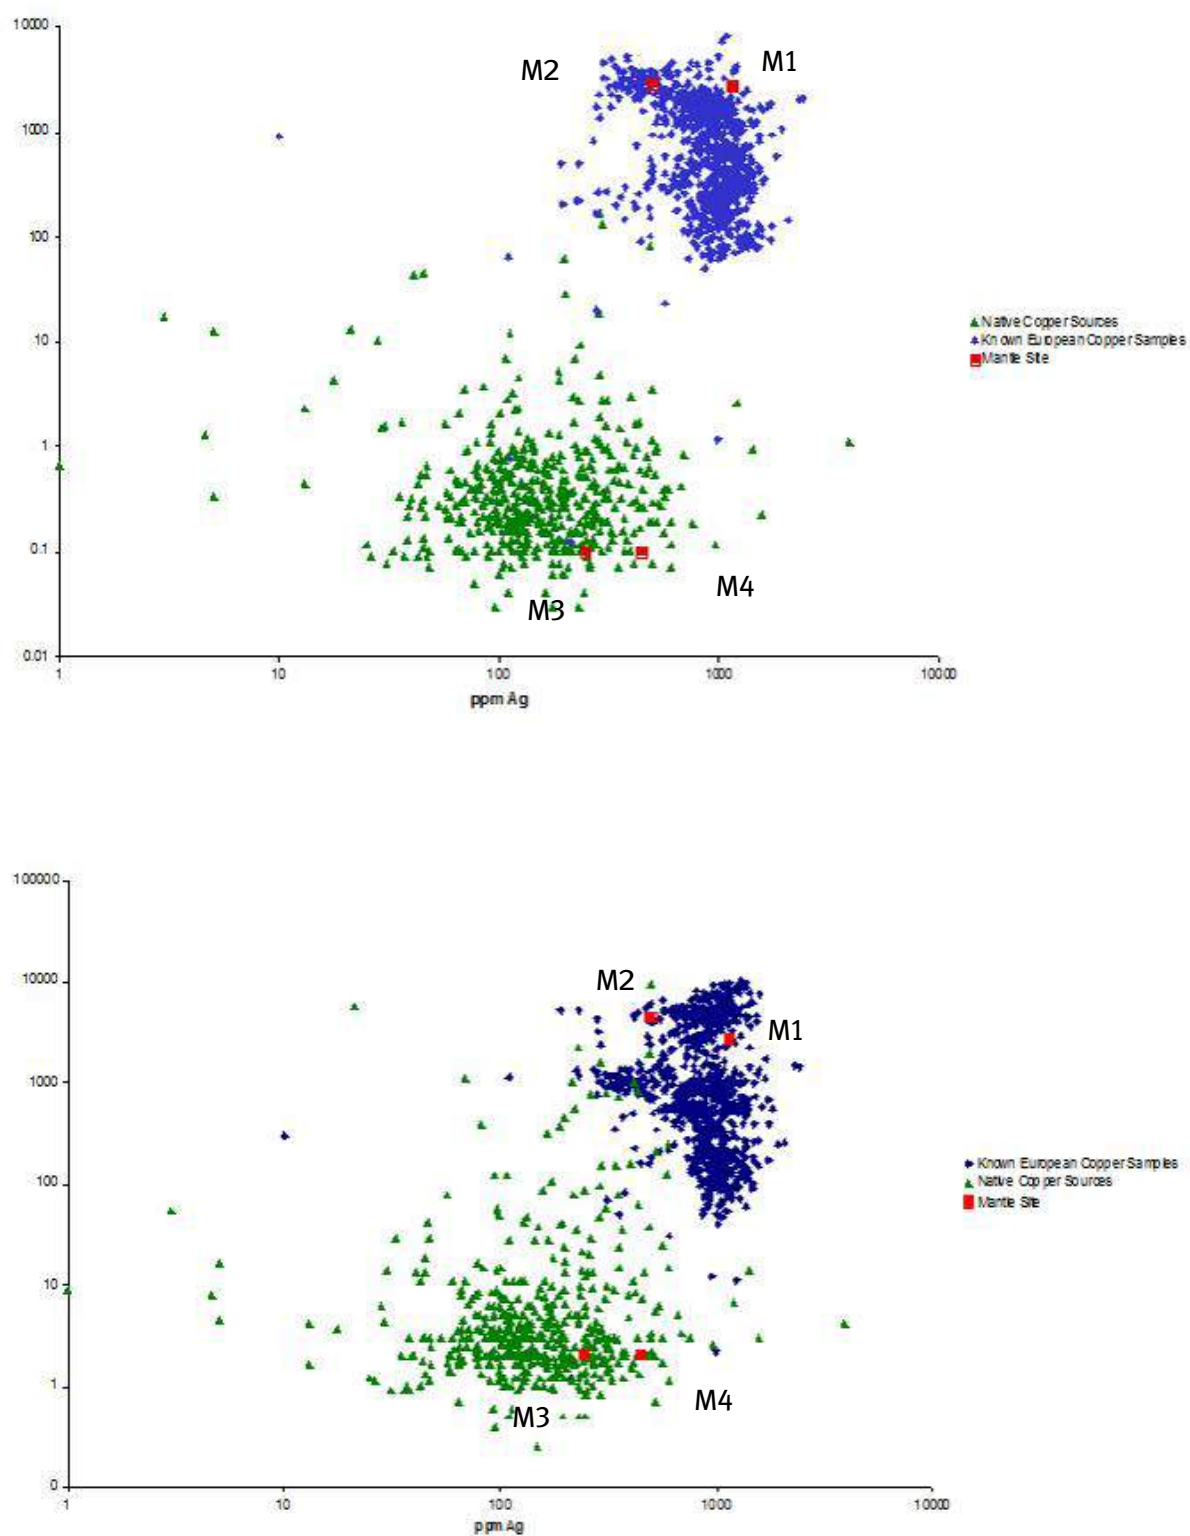

Figure 58: Bi-plots for Copper Artifacts

The bead (Cat. #M3) and the piece of scrap (Cat. #M4) were manufactured from native copper that was either mined from the massive deposits found in the Lake Superior basin or from pure nuggets or float copper found in glacial deposits and stream beds. The copper was heated to anneal or soften it and then cold hammered to the desired shape. There is no evidence that copper was smelted or poured into moulds in precontact North America. The source of the European copper is unknown at this time, however, research is being undertaken to source the copper artifacts, the results of which will be published in a separate article.

## 6.3 Iron Tool

### 6.3.1 Introduction and Visual Examination

A single heavily corroded piece of iron was recovered from a pit feature (F1464) under the bunk line of House #28 (Figure 59). It was discovered at the bottom of an otherwise sterile pit at a depth of 41 centimetres (Figure 60). The indistinct nature of the fill suggests the feature was excavated for the purpose of burying this object. House #28 is associated with the second phase of the Mantle village occupation. As no other historic features or historic artifacts were documented within this area, the iron piece and the feature were treated as part of the precontact site.

Figure 59: Location of Feature 1464

- 4 Yellowish-brown subsoil

Figure 60: Plan and Profiles of Feature 1464 in House 28 at the Mantle site (AIGt-334)

The dimensions of the iron piece are 72.6 x 25.2 x 9.0 millimetres in length, width, and thickness and it weighs 60.4 grams. The surface accretions are so dense that the original shape of the object is obscured (Plate 89). Due to the importance of the presence of an iron artifact on an early sixteenth century site, it was decided that a number of scientific applications would be explored in order to aid in the identification of the piece.

Plate 89: Mantle Iron Tool (Cat. #M5)

Prior to any scientific techniques being undertaken, it was important to determine the extent to which the object had deteriorated. It was possible that the corrosion rate may have been such that mineralization was complete and no metal core survived. Also of concern was the depth to which the corrosion may have penetrated the artifact. Although it was perceived to be solid, the artifact might actually have been deeply fissured by cracks which, if the corrosion product was acting as a cementing material and was removed during investigations, might have result in the fragmentation of the piece. In some circumstances, when an object is heavily or even completely mineralised, radiography can provide information on the original structure as its form can be preserved or fossilized in the groundmass of the corrosion product.

Starting with the hypothesis that the artifact represented a) an object cut from an iron axe and reworked, b) was the blade from a wood block plane, c) was a standalone tool or d) some other tool form, X-radiography was undertaken in order to identify the shape and structure, manufacturing technology, surface features and condition of the artifact. A series of X-rays were performed at an industrial facility that provided an array of specialty services (relating to the maintenance, inspection, quality control and

construction of mechanical and piping systems) that produced high quality radiographs (both digital and film) enabling the interpretation of even the most subtle discontinuities and variations in the radiograph. Medical diagnostic X-ray systems were not used as they are designed to operate with a very short exposure time, high current and low kV levels. The ability to control high kV levels and exposure times was critical in being able to document evidence of surface features and modification marks.

### **6.3.2 Results of X-Radiography**

The first set of X-rays taken focused on the shape and structure of the object. Plates 90-91 illustrates that the core of the piece is solid and intact as no cracks are present in the film. The tool has a bevelled bit and the poll is tapered. The parallel edges of the tool show no striations and therefore no evidence that they have been ground. A thin fracture line can be seen at the poll of the tool and likely represents where this piece was broken/separated from the original tool.

Plate 90: Plan View of Mantle Iron Tool (Cat. #M5)

Plate 91: Profile View of Mantle Iron Tool (Cat. #M5)

The X-ray also provided information regarding the manufacturing process from details of the microstructure of the iron visible in the film. In order to place the tool in a time frame in line with the dates attributed to the Mantle site, it was first critical to determine whether the piece was manufactured from wrought or cast iron, as small cast iron tools would not have been made prior to the eighteenth century. Cast iron exhibits characteristic features which are identifiable on X-rays, as having a coarse granular texture and the appearance of dark circular voids (porosity) created by gas trapped in the metal during the cooling process. On the other hand, due to prolonged unidirectional hand hammering, the

microstructure of a wrought iron object becomes elongated and fibrous which shows on radiographs as slightly irregular light and dark bands parallel to the object's main axis. This fibrous patterning characteristic of wrought iron is present on the X-ray of the Mantle iron tool (Plate 92).

Plate 92: Profile View of Mantle Iron Tool (Cat. #M5)

Observing incised and/or scored lines, tool marks and forge marks depend on more subtle variations in the radiographs. This relies on combining techniques of both image capture and viewing in order to draw out this information. Through multiple incremental exposures, over-exposing the images, and using specifically designed edge and density filters, we were able to investigate differences in the metal thickness. This led to the identification of two marks and several other possible discontinuities (Plates 93-94).

The first mark, a horizontal line with an offset square and an angled line, was the most robust mark to be impressed into the piece (Plate 93). It was identified at all levels of imaging due to its well defined depth. The second mark is composed of two circles of common diameter connected by simple lines (Plate 93). This impressed mark is much shallower in depth and was only identified during the longest exposure times to the X-ray beam and use of a density filter. To explore the discontinuities, a filter designed to extract the hard edges of the corrosion pitting was applied. However, as can be seen in Plates 93, a level of uncertainty exists as its form is not clearly defined. At this time, it is believed that this discontinuity may be a horizontal bar/ "I" shape form or it represents corrosion terracing on the tool's surface. We will therefore be undertaking a series of microfocus X-rays to further define the shape of each of the marks and discontinuities. The results of this work and the above imaging techniques will be reported on in a future article.

The detection of the marks at differing levels of imaging can be related to the order in which each mark was struck into the iron during the last stages of the forging process. Marks are struck into a metal form when it is "red hot" and are referred to as "hot stamps." As the iron cools, the penetration of the stamp into the iron changes depth, with the first struck marks always the deepest. As the metal cools, subsequent marks struck become shallower and less defined. Therefore on the Mantle iron tool it can be postulated that the offset square was struck first, the "I" (if a mark) struck second and the circles struck third.

A second series of X-rays was undertaken at the Royal Ontario Museum with an experienced metals conservator, Susan Stock and art conservator Heidi Sobol, to confirm the presence of the marks identified. The offset square mark was confirmed and two discontinuities were identified in the vicinity of the circles and "I" mark (Plate 94).

Plate 93: Marks struck on the tool and area of discontinuity (X-ray with filter).

Plate 94: Second X-ray series showing marks struck on the tool and area of discontinuity (X-ray with filter).

### **6.3.3 Research into Origin of the Mantle Iron Tool**

In researching the early sixteenth century European presence in the New World as well as iron sourcing, mining and processing, and importing and exporting trends during the late fifteenth and sixteenth centuries, it was determined that a Basque origin was a strong possibility for the Mantle iron tool. With dependence across Europe on Basque iron by at least the second half of the fifteenth century, the proliferation of iron mines, forges, workshops and craftsmen earned the Spanish provinces of Basque Country a reputation as an area of excellent quality ore and producers of excellent iron products. England alone drew some 90% of its supplies from the Spanish Basques provinces, with imports totalling 3,000 tons of Basque iron annually which speaks to the level of Basque output for the period (Childs 1981). England's own small production was not the result of lack of ore, or inadequate skills, but from lack of incentive to invest in its mainly phosphorous ores when foreign goods were more easily and cheaply accessible (Childs 1981). In addition, numerous archaeological sites along the coast of Newfoundland and Labrador evidenced the strong Basque presence during the sixteenth century (Huxley Barkham 1980-1881, Story 1982, Huxley Barkham 1984, Huxley Barkham 1987, Huxley Barkham 1989, Bakker 1989, Tuck and Grenier 1989, Fitzgerald 1991, Turgeon 1990a and 1990b, Barkham and Barkham 1993, Biggar 1993, Fitzgerald 1993, Proulx 1993, Fitzgerald 1995, Barkham and Barkham 1996, Barthelmess 2000, Martijn et al. 2003, Barkham 2003, Fitzhugh and Phaneuf 2008, Grenier et al. 2008, Biggar 1911 and 2010). Many site reports contain large assemblages of iron tools and historical research detailing the known interaction of Basque whalers with local Algonquian and/or St. Lawrence Iroquoian groups who were known to interact with the Huron-Wendat (Story 1982, Bradley 1987a and 1987b, Bradley and Childs 1987 and 1991, Bakker 1989, Tuck and Grenier 1989, Fitzgerald 1990, Turgeon 1990a and 1990b, Light 1992, Fitzgerald et al 1993, Fitzgerald 1995, Bradley et al. 1998, Barthelmess 2000, Bradley 2001, Ehrhardt, 2001, Ehrhardt, 2002, Fitzhugh and Phaneuf 2008, Grenier et al. 2008).

A literature search was also undertaken in an attempt to identify the origins of the marks. It was discovered that the marks likely represented merchant mark and/or forge/blacksmith marks and up to seven unique marks could be present on a piece. Merchants' marks/forge marks/armourer marks/blacksmith marks etc. should all be seen in the context of the widespread use of personal identification marks in the medieval through to early modern periods. They were used by all classes of people and organizations. In a society which was, for the most part, illiterate, it was important to have a series of symbols which could be easily identified, unambiguous and capable of being reproduced quickly (Walsh 1993). Trade laws and guidelines provided the basis for the bylaws of every guild throughout Europe in the thirteenth and fourteenth centuries (Childs 1981; Walsh 1993; Adamwicz 2007). With time, the symbols associated with a trade began appearing on the tools representing the name or stamp of the maker, the source of the goods, and acted as a quality guarantee used by businesses to uniquely identify their products in the marketplace and vie for consumer loyalty. By the sixteenth century merchant marks became so numerous that government offices in Europe initiated a registration process for new designs, a tradition that continues to this day (Childs 1981; Walsh 1993; Adamwicz 2007). For example: armourers, gold and silversmiths, tapestry makers, coopers, printers and book-binders all placed marks on their products. Some marks, such as the simple incised designs used by blacksmiths, signify workmanship, acted as a function of payment and were a mark of quality control (Walsh 1993; Stalley 1987). Marks were in widespread use throughout the fifteenth and sixteenth centuries and began to go out of fashion gradually during the latter part of the seventeenth century but continued to be in general use well into the following century (Stevenson 1954).

While researching Basque culture, its merchants and iron industry, the signatures of Basque individuals were noted for the designs at their ends. According to Bass (2008), this flourish was legally more important than the signature itself because it was difficult to duplicate and without it, a signature was not authentic. Sometimes, the symbol alone was all that was required. The development of a personal identifying mark was taught at a young age, however, this practice came to an end in the mid-nineteenth

century (Bass 2008). These personal identification marks became integral to the Basque economic system and were included as part of the mark series on all goods.

Examination of iron artifact collections housed at Aizpetta and Mirandaola, Guipuzcoa, Basque Country resulted in the documentation of two marks similar to ones on the Mantle iron tool, thus signifying that our tool was indeed Basque in origin (Carnevale et al 2012). These included one on a meat cleaver and one on sheep shears (Plates 95-96). Also documented was the common Basque practice of marking iron tools of all types and forms with marks. Further investigations into artifacts recovered from Red Bay, Newfoundland also resulted in the identification of similar circular marks on Barricas, or wooden casks (Plate 97). An examination of archival sources revealed that the combinations of circles were used by some trades as a numerical short hand as well as part of a personal mark (Turgeon and Picot-Bermond 1987). These marks were scribed in warehouses to identify the casks while transferring them from one merchant to another. In addition, Basque millers traditionally employed a separate number system of unknown origin. In this system the symbols are either arranged along a vertical line or horizontally (Sorondo 1988). On the vertical line the single digits and fractions are usually off to one side, usually at the top (Sorondo 1988). When used horizontally, the smallest units are usually on the right and the largest on the left (Sorondo 1988). It is therefore possible that blacksmiths, forges and the iron industry used a similar system or had their own series of marks as well. Research into identifying the ironworks that used the marks present on the Mantle iron tool is ongoing. The names and location of 201 forges and the names of 49 prominent merchant families who owned foundries in the Guipuzcoa study area have been identified (Carnevale et al 2012). It is possible that notarized documentation and judicial papers could provide an identity to the marks on the Mantle iron tool.

A number of unique Basque tool forms were also documented while in Basque Country, in particular, a Podadera, used by the Spanish Basques as a multipurpose tool. It had a shape and size range reminiscent of the Mantle iron tool (Plate 98; Carnevale et al, 2012). This tool is used by the Spanish Basques to clear and cut small trees, scrub and vines. The collections of artifacts recovered from sixteenth century whaling stations in Labrador will be examined for similar tool forms to the Podadera and the Mantle iron tool as well as examined for marks.

Plate 98: Various Basque Podadera tools

## 6.4 Discussion

While the discovery of the European items, especially a Basque iron tool, was unexpected on a site of this time period in southwestern Ontario, it was not to Dr. James Tuck (personal communication with Ron Williamson, 2011) who felt that if more early sixteenth century sites were completely excavated in the Great Lakes Region, additional such objects would be found given the considerable Basque presence on the east coast by the turn of the fifteenth century and the known interaction of Basque whalers with local Algonquian and/or St. Lawrence Iroquoian groups (Biggar 1993, Biggar 2010). The movement of the tool, and presumably the European copper, simply followed the same routes that ceramics and marine shell had a half century earlier. The burial of the iron tool, under a bunk line where valuables were sometimes buried according to later Jesuit observers, is fully in keeping with the ways in which these objects may have been viewed during this period.

## 7.0 PLANT REMAINS

*Stephen G. Monckton and Crystal L. Forrest*

### 7.1 Introduction

A total of 710.5 litres of soil was recovered from 212 features at the site (Appendix L). All samples were analysed to provide an opportunity to evaluate both plant use and the spatial distribution of plant material across the site. The following is a review of analytical methods and offers interpretations of the findings.

### 7.2 Recovery and Analytical Methods

Soil samples were floated using the double-bucket method. A 300 micrometer screen was used to collect the light fraction, and a 2.0 mm screen for the heavy fraction. Samples were wrapped in cloth to dry. After being air dried, light fractions were weighed and passed through a series of screens to facilitate sorting. Material larger than 2.0 mm was separated into sample components that were weighed and counted (Appendix L - Table 1). Material below the 2.0 mm screen was sorted for seeds only (Appendix L - Table 2). Only charred material was recovered, assuming uncharred plant material was modern and intrusive. Breaking wood charcoal fragments in half provided a clear transverse view of tissue for identification. For consistency, objects smaller than 2.0 mm across the transverse section were deemed unidentifiable. Several specimens smaller than this provide good identifications, but not consistently enough to prevent bias in favour of some genera over others. Modern charred comparative material aided identifications where necessary. Appendix L - Table 3 contains wood charcoal results in the form of fragment numbers.

Larger seeds such as maize, acorn fragments, or other nuts were counted and their fragments were weighed. Maize kernel number for each sample was estimated on the basis of the weight of fragments and converted to whole kernels based on the known weight of 100 whole kernels. This was to prevent a bias in favour of maize fragments.

### 7.3 Results

Tables 1-4 in Appendix L illustrate the botanical contents of the site. The samples have been attributed to longhouse and external longhouse features to enhance the interpretation of the spatial distribution of plant remains. These will be discussed in the sections below.

It is no surprise that the relatively large number of samples from the site as a whole reveal examples of all the Iroquoian cultigens: Maize (*Zea mays*), bean (*Phaseolus vulgaris*), cucurbit/squash (*Cucurbita pepo*), sunflower (*Helianthus annuus*), and tobacco (*Nicotiana rustica*). Maize is the most abundant, followed by large quantities of sunflower. Bean, cucurbit, and tobacco are comparatively rare. The relative contributions of these cultigens to the site deposits are broadly similar to that of other Iroquoian sites.

Collected plants include: the common fruits of bramble (*Rubus sp.*), strawberry (*Fragaria sp.*), cat-tail (*Typha latifolia*), seeds of sumac (*Rhus typhina*), chenopod (*Chenopodium sp.*), spikenard (*Aralia sp.*), a small grass (cf. *Echinochloa*), purslane (*Portulaca oleracea*), black nightshade (*Solanum americanum*), hawthorn (*Crataegus sp.*), plum (*Prunus sp.*), ironwood (*Carpinus caroliniana*), erect knotweed

(*Polygonum erectum*), elderberry (*Sambucus sp.*), pincherry (*Prunus pensylvanica*), cleavers (*Galium aparine*), delta seed (*Leucadendron sp.*), grape (*Vitis labrusca*), peppergrass (*Lepidium virginicum*), knotweed/sedge (*Carex sp.*), amaranth (*Amaranthus retroflexus*), barnyard grass (*Echinochloa crus-galli*), pokeweed (*Phytolacca americana*), and service berry (*Amelanchier arborea*).

Wood charcoal is dominated by maple (*Acer saccharum*) and beech (*Fagus grandifolia*), followed by ash (*Fraxinus sp.*), elm (*Ulmus americana*), ironwood (*Ostrya virginiana*), white pine (*Pinus strobus*), cedar (*Thuja occidentalis*), and red and white oak (*Quercus rubra* and *Q. alba*). A significant number of the unidentifiable fragments that were designated as deciduous tree wood are diffuse porous – typical of the maple, but possessing insignificant rays. In the case of some very small fragments, these could also be semi-diffuse porous ironwood.

## 7.4 Discussion

The economic importance of maize is well attested by early visitors to the lower Great Lakes region whose references to the plant and contexts of its use abound in their writings (e.g., Thwaites 1896-1901). Researchers have since considered maize and the two other most commonly mentioned cultigens (beans and “squash”) to be the mainstay of peoples’ diet. The importance of maize has been supported in part by the consistency of some of the early historical records, but also by a growing body of paleoethnobotanical evidence (for a wider perspective see Crawford and Smith [2003]), and chemical and morphological analyses of human bone (e.g., contributions in Williamson and Pfeiffer [2003]). While there is recent evidence of maize in the Northeast as early as 2000 BP (Thompson et al. 2004), most researchers agree that maize became an established food staple early in the Iroquoian tradition a thousand years later.

Maize occurs in the form of cob fragments, stems, and maize kernels. These are usually quite fragmentary depending on the context. Kernels are the most delicate of maize remains and usually present themselves as small fragments with an identifiable thin epidermal/seed coat surface and obverse mass of endosperm tissue. These kinds of kernel fragments are clearly not grouts resulting from seed grinding, but fragmented kernels that were initially dry enough to be charred without exploding. It is quite uncommon to find large quantities of intact, measurable kernels. The latter situation may arise where substantial quantities of maize kernels have been spoiled (i.e., burned) and left in a deposit that remained undisturbed. The key factor here is that large quantities were deposited over a short period of time, increasing the probabilities of some kernels remaining intact. Contexts in which such a scenario appears to have occurred at Mantle are the fills of support post features, basal midden deposits, and deep refuse filled pits.

Many Iroquoian assemblages have sparsely distributed maize in virtually every feature excavated. These are usually comminuted, and their numbers must be estimated by their weight. Bean and cucurbit, by contrast, are much less common in most deposits. Bean, for example is mentioned frequently in the reports of the Jesuits in the 17<sup>th</sup> century (Thwaites 1896-1901; 2: 21; 2: 165, 207, 298; 5: 282; 10: 103; 13: 41, 75, 189; 15: 153; 17: 17; 21: 195; 38: 245; 40: 255; 42: 197; 43: 183; 50: 145; 54: 207; 59: 129; 67: 213; 68: 137), but its preparation for food appears to all but eliminate it from the record at many archaeological sites. Unusual preservation, such as the accidental burning of food in areas unrelated to cooking, appears to have occurred at the protohistoric Huron Auger site (Latta 1985). This may have been responsible for the charring of one of the largest measurable samples of bean in eastern North America (Monckton 1992:37). Similarly, cucurbit is archaeologically elusive, but is frequently mentioned in ethnohistoric reports (Thwaites 1896-1901; 2: 21; 2: 165, 207, 298; 15: 153; 21: 195; 38: 245; 43: 183; 50: 145; 54: 207; 59: 129; 67: 213; 68: 137). The Mantle site yielded seven charred specimens. Preparation for consumption often involved cooking them whole in ashes (Thwaites 1896-1901; 10: 103; 15: 161-162), or cutting them into small pieces for adding to the *sagamité* (Wrong 1939: 107). At most Iroquoian

sites, curcurbit remains recovered are in the form of seeds rather than rind. The curcurbit remains from the Mantle site are an exception to this: several peduncles were recovered at Mantle. Peduncles were also common at the Auger site, and Monckton (1992) suggested in that instance that there must have been special conditions of preservation and deposition. This may also be the case at Mantle.

Remains of sunflower, on the other hand, are fairly common in Iroquoian deposits, while mentioned rarely by early historic observers in the *Relations* (Thwaites 1896-1901; 37: 105; 65: 129), or by Champlain (Biggar 1922-1936; 3: 50). Sunflower remains were found in large quantities at the Mantle site as well. Most remains consist of small fragments of achenes (sunflower shell). It is likely that this cultigen is better represented in the archaeological record because of its distinctive micromorphology and durability. Beans, in contrast, are easily recognized whole, but tiny fragments of its tissue are less easily distinguished from the meats of nuts for example.

Unlike the other cultigens, tobacco is represented by extremely small and delicate seeds. When considering the prodigious quantities of seeds this plant produces (up to a million per plant) and the frequency of ceremonial activity surrounding it (Thwaites 1896-1901; 3: 117; 5: 113; 7: 137, 139; 17: 81-83, 127; 18: 187; 20: 187; 32: 229; 38: 253), it is surprising that more are not found in the archaeological deposits despite their fragility. Ceremonialism involved tobacco being thrown onto the fire, sometimes in “cakes” (Thwaites 1896-1901; 10: 159; 13: 209; 23: 55), and direct flame would have incinerated most seeds. Charring without complete destruction requires indirect heat by fire. Quantification and assessment of tobacco’s importance in a community is therefore compromised by these factors. Surprisingly, there were few tobacco remains recovered despite the rich ceramic and stone smoking pipe assemblage.

#### 7.4.1 Collected Plants

The most abundant category of plant remains apart from wood charcoal is fleshy fruits. At Mantle, bramble and strawberry are the most frequent fruits with significant numbers being recovered from interior longhouse features. This is at odds with many settlements in southern Ontario. At the Middle Iroquoian Myers Road site, for example, yields for fruit (40%) rival that of maize (39.6 %) (Monckton 1998), and were recovered from exterior longhouse deposits. This suggests the use of these features in summer in those locations, perhaps associated first fruit festivals (Waugh 1916:125-128). In the case of the Mantle site, these outdoor activities certainly seem to have been occurring since large quantities of fruit seeds are encountered outside of longhouses; however, a far greater number of seeds were recovered from within longhouses. This is likely evidence of fleshy fruits being dried and stored for winter use, perhaps an activity more intensively pursued at Mantle than at other pre-coalescent sites due to the large population at the site. There would have been a substantial need to prepare for winter scarcity in case of crop failure that may have resulted in more intense gathering and preparation of wild plant foods. Monckton (1992:93-94) has suggested that areas around large villages may have been purposely maintained for collection of wild, anthropogenic foodstuffs.

Other plant taxa found at Mantle are also widespread in Iroquoian settlements, though in smaller numbers. The most common ones are cat-tail and sumac. The Jesuits may have been referring to cat-tail in their accounts of rushes used to cover the longhouse floors and roofs (Thwaites 1896-1901; 42: 205; 58: 209; 59: 129, 133, 155), although the plant was found in exterior rather than only interior longhouse features. Feature 863 in House 12 contains over 400 cat-tail seed specimens, considerably more than any other feature and perhaps indicative of an intact living floor. With respect to sumac, which commonly grows in disturbed areas, various Anishinaubeg groups are known to have used the plant in beverages, medicines, and for smoking (Smith 1933:38). The majority of sumac seeds were recovered from within longhouses.

### 7.4.2 Wood Charcoal Distribution

Wood charcoal data indicate that the most frequently used tree species include maple, beech, ash, elm, and ironwood, respectively (Figure 61). The wood charcoal data from Mantle were used to investigate whether or not resource utilization changed over time by examining proportions of maple and beech wood charcoal from houses determined to be from the early versus later occupations of the site (Figure 62). Nineteen early houses and 12 late houses were identified (following Birch 2010 and see Chapter 2, this report) and compared, and the differences between maple and birch wood charcoal distributions were examined for statistical significance using the Chi Square statistic. The differences in distribution between maple and birch wood charcoal in early versus late houses were not found to be statistically significant ( $X^2 = 0.097$ , alpha level of significance 0.05, one degree of freedom).

While it has been documented that house and support posts at ancestral Neutral sites were constructed of cedar (because of relatively slow rate of decay) (Warrick 1988), it appears not to have been the case at Mantle or other West Duffins Creek villages. Most support and house posts at the site were found to contain maple, beech, and ash wood charcoal reflecting the overall charcoal present at the site and climax hardwood forest more generally (Appendix L - Table 4). Four of these posts contained cedar, although only one of these four was associated with a longhouse (House 71/72/73). Soil samples from House 53, which likely burned down (see Chapter 2) and therefore contained a sizeable amount of wood charcoal, are consistent with the general pattern at Mantle.

Figure 62: Distribution of maple and beech wood charcoal in early and late houses

## 7.5 Site Comparisons

The Iroquoian Robin Hood, Draper, and White settlements are located within a 10-kilometer radius of Mantle. Robin Hood and White likely contributed to the formation of the Draper site, the community of which then moved to Spang and then Mantle (Birch 2010, Birch and Williamson 2013). Plant remains from these sites provide comparative data although an unprecedentedly large volume of plant remains was recovered from Mantle, which contributes to bias when comparing Mantle with much smaller volumes of plant remains from other sites. The sites chosen for comparison were not randomly selected from those within a 10-km radius; rather, they were opportunistically selected due to the availability of data pertaining to plant remains from these sites. The compilation of the comparative data from site reports, theses, and publications prepared by different researchers adds an additional measure of complexity. Subtle differences in data collection and presentation among the researchers may result in additional error when these data are compared to one another.

To minimize bias, when plant remains from these sites were compared, only flotation samples were used. Manually collected finds, while valuable for measurements of seed morphology, are inherently biased in favour of larger objects visible to the naked eye. Flotation samples, on the other hand, provide the entire range of seed size and frequency per litre of soil. Figure 63 illustrates the relative frequencies of major seed categories: cultigens, fleshy fruits, greens and grains, other plant taxa, unknown plant taxa, and unidentifiable specimens. The latter three categories are grouped together for the purposes of this analysis because these categories are not employed in a uniform manner in the source publications.

Figure 63: Seed Category Distribution by Site

The most obvious difference among the sites is the large proportion of fruit seeds recovered at Robin Hood, one reason why it was originally thought to have been an agricultural cabin site occupied in summer months only (Williamson 1983). Large quantities of fruit were also recovered at Mantle as discussed above.

Figure 64 shows percentages of types of wood charcoal from the Mantle, Draper and White sites. No data were available from the Robin Hood site. Wood charcoal from these sites shows the general trend in favour of maple and beech dominated forests. The inhabitants of the Mantle site appear to have relied more heavily on ash and made use of white pine, cedar and oak in small quantities, while those at the Draper and White sites used elm more frequently and used birch, hickory, walnut and cherry from time to time. These differences between Mantle and the other sites can be explained by variations in forest structure and patchiness of the local forest stands, and by the very close proximity of the Draper and White sites (resulting in exploitation of the same biotic niche).

Figure 64: Wood Charcoal Comparisons by Site

## **8.0 ZOOARCHAEOLOGICAL REMAINS**

*Suzanne Needs-Howarth*  
*Perca Zooarchaeological Research*

### **8.1 Introduction**

The Mantle faunal assemblage consists of 37,542 specimens, including: shells of bivalves and gastropods; the exoskeleton of a crustacean; bones of fish, amphibians, reptiles, and birds; and bones, teeth, and antler of mammals. Within these eight zoological classes, 67 unique taxa were identified. It is estimated that the following analysis represents well in excess of 95% of the Number of Individual Specimens (NISP) for the site. A complete inventory of all faunal specimens is listed in Appendices L and M.

### **8.2 Method**

#### **8.2.1 Recovery**

The faunal remains from the Mantle site were recovered by manual soil screening with 6 mm mesh (95% of NISP) and floatation heavy fraction screening with 3 mm mesh (5% of NISP). Faunal recovery was excellent within the restrictions of the 6 mm mesh. A large portion of the fish bone is smaller than 6 mm in at least one of its dimensions, yet it was still recovered in the 6 mm mesh. Unfortunately, the use of 6 mm mesh does introduce a systematic bias against some small taxa and small elements or fragments from bigger taxa. The 5% (n=1,914) of the faunal assemblage amassed by screening with 3 mm mesh is derived from the extensive floatation program. A qualitative comparison of the two subsamples indicates that the 6 mm mesh size was probably large enough to catch most of the bone originally present in the archaeological deposits with the exception of smaller bones or fragments of larger bones of fish and smaller mammals. The posterior vertebrae of smaller eels, for example, would fall straight through the dry screening mesh. As expected based on quantification by other researchers (e.g., Stewart 1991a), fish recovery increased within the floatation samples because of the better recovery of thin ribs and spines (which, when oriented on their long axis, would fall through the 6 mm mesh). Small items such as squirrel toes were absent even in the heavy fractions from flotation.

#### **8.2.2 Lab Procedures**

The bone was washed in the lab by ASI staff by agitation in water, and where necessary gentle brushing with a soft toothbrush. It was then sorted by taxonomic class, and heat-altered specimens were separated from the rest. Specimens were repacked in the ASI lab in polyethylene zipper bags (for shell and fish remains) or paper bags (for other classes), within larger paper bags according to provenience. These paper bags were then placed inside cardboard boxes.

Specimens were classified to lowest possible taxonomic level according to the Linnaean taxonomy (kingdom, phylum, class, order, family, genus, and species, and subspecies) by Suzanne Needs-Howarth (SNH), of Perca Zooarchaeological Research. They were classified through direct comparison with skeletons of known age and sex in the Howard Savage Archaeo-Osteology Collection in the Department of Anthropology, University of Toronto. The specimens were also described in terms of cultural and natural modifications and the former were detected using a lamp at three times magnification.

Element and portion present were noted only for those bones that were further classified below taxonomic class, except for larger mammal bones, which were separated into “longbone” and “indeterminate.” This

was done because this information can potentially provide information on processing. For mammals, the portion present, side of origin (right or left), and indicators of skeletal age were noted where possible. Taxonomic classification of the Mantle site faunal assemblage follows the Integrated Taxonomic Information System ([www.ITIS.gov](http://www.ITIS.gov)).

The total number of bones that can be considered to have been contemporaneous with site occupation is 37,542. Bones that are clearly not part of the pre-contact archaeological assemblage because of taxon (e.g., pig), modifications (i.e., cuts made with a metal meat saw) or skeletal completeness (e.g., entire toads, perfectly preserved bones of woodchucks that apparently died in their burrows) were categorized as “recent/intrusive.” A total of 7,513 specimens was attributed to: historic-period pig and cow burials (this excludes the horse burials that had already been identified by ASI lab or field staff); plough-caused historic-period contamination of the Iroquoian levels; clearly intrusive rodents; and other intrusive material. All of these recent and intrusive identifications were placed in a separate database for ease of data manipulation (see Appendix M for summary by context type). Note that additional sheep, goat, pig, cow, and horse specimens may be unintentionally included among the unidentified larger mammals (possible candidates are flagged as “recent?” in the main database). It is also possible that some of the bones of the wild taxa also post-date the Mantle village occupation. Additional bones that appeared recent on the basis of their taphonomic characteristics (patina or cortical bone condition) are noted in the comments field of the database, but are included in the main database and the discussion.

### 8.2.3 Quantification

#### *Taxonomic Categories*

In the catalogue (Appendix M – Table 1), uncertain identifications are designated by a cf. in a separate field. The cf. should be read as preceding the binomial (in the case of monotypic genera) or inserted between the genus and species. For ease of presentation in the tables, all uncertain identifications have been merged with certain identifications.

When there are two osteologically similar species, one of which occurs in the area and the other of which does not, it is assumed that the bones present at Mantle must be from the local species. For example, osteologically speaking, many of the *Odocoileus virginianus* (white-tailed deer) identifications could also be *Odocoileus hemionus* (mule deer), but, given that that species’ distribution is far from Ontario, it is extremely unlikely. So, rather than adding the identification level of *Odocoileus* sp., all *Odocoileus* remains are classified as white-tailed deer.

The reference collection used is fairly complete, but there are some gaps. The collection contains only one of the three possible species of both *Ameiurus* and *Lepomis*, and lacks some elements of the two species of *Micropterus*. Genus-level identifications for these three genera in the database could possibly be narrowed down to species-level identifications with the aid of a more complete reference collection.

Morphological similarities between the bones of two or more species whose distributions and sizes overlap can make identification below family or genus level difficult. Examples of such taxa are *Coregonus*, the various suckers, vertebrae of Cypriniformes and Perciformes, as well as the various ducks. Fish vertebrae are not uniformly easy to identify among taxa. *Coregonus*, eel, and Catostomidae vertebrae are highly distinctive, whereas Centrarchidae and Percidae are much less distinctive, partly because they are often very small.

This difference in identifiability causes some of the variation in percentages of vertebrae; processing likely also causes variation, as does screen mesh size.

Sometimes it is also difficult to distinguish fragmentary ribs and vertebrae of deer from those of sheep or goat. This has resulted in some “Artiodactyla deer or sheep size” identifications. The same goes for the larger Artiodactyla. Note that because of historic contamination of the ploughzone, the category “Aves chicken/goose size” may well include some chicken and domestic goose, and the category “Artiodactyla wapiti, moose or cow size” may include cow. Historic contaminants may be included in other categories of unidentified remains as well.

In the text below, taxa are mostly presented in taxonomic order, but are sometimes grouped by habitat and habits to facilitate discussion. For the convenience of the reader, in the case of unusual finds and of rare taxa that may have had special ideological significance for the Mantle inhabitants, the catalogue number and provenience (northing and easting) are provided.

### ***Number of Identified Specimens (NISP)***

This basic unit of measurement refers to shell or bone counts, including entire skeletal elements, teeth and fragments thereof (Appendix M – Table 2). The possibility of element interdependence is a caution against excessive reliance on percentages by element or by age. This is especially true for the mammal vertebrae, as there are many in the body, each with possibly three or more parts (the two epiphyses and the body, which in young animals itself may consist of three unfused parts). This means that, provided that fragmentation rates are constant, there is an inherent bias towards younger animals. For example, a complete bone with unfused epiphyses would be counted as NISP=3, whereas a complete bone with fused epiphyses will be counted as NISP=1.

Every effort was made to join up parts of the same bone, as this increases the likelihood of making a lower-level taxonomic identification. Bones that could be mended on recent breaks or at the bone ends are counted as one because the parts would have been attached when deposited. Items that fit together on old breaks were counted as two because they were likely separate when deposited.

When remains are found in two non-adjacent or non-touching units, it is more likely that they are from different animals – although in the case of midden-like concentration # 2 and midden-like concentration #3, the material may have been mixed.

Bivalve shells represent a challenge in quantification, as they are often very fragmented and sometimes powdery. Therefore, for bivalve shells, the minimum number of valves (left and right) that could accommodate the remains found in each bag was estimated, and that estimate was entered as the NISP. As a matter of expediency, the side of the body from which they originated was not determined.

When quantifying and comparing mammalian species, it is important to remember that smaller bones of the smaller species are going to be underrepresented because of recovery method. For example, the intact proximal phalanges of dogs will be retained in 6 mm mesh, while those of squirrels will not. The same applies to sesamoid bones: those of deer will be retained, while those of dog and smaller mammals likely will not. In order to avoid “inflating” the counts of deer bone compared with smaller mammals, all sesamoids were categorized to mammalian size class only, although the 101 sesamoids of “Mammalia pig, bear, deer size” are likely all deer based on size and morphology.

### ***Minimum Number of Individuals***

Minimum Number of Individuals (MNI) estimates were calculated conservatively, using element duplication, side, size, and age. Taphonomy makes comparing between classes, and even within classes, difficult, as different animals will have been processed differently, and butchering and fragmentation rates

will lead to more or less element interdependence (for example, a fragmented deer cranium, where an NISP of 5 may represent MNI 1, or tens of fragmented ribs and spines from the same individual fish).

As first demonstrated by Casteel (1976-77) and more recently by Lyman (2008:48-56), there is often a predictable relationship between NISP and MNI. As NISP increases, it takes progressively more specimens to add a new “individual.” Taxa with a low NISP often have a proportionately high MNI, because even a single bone results in the tabulation of one individual.

At a site with both small mammals and large mammals, it is interesting to compare NISP with MNI. The bones of the small mammals are less likely to be broken up during preparation or consumption or disposal than those from larger mammals. This means that breakage may reduce their identifiability. On the other hand, if it does not, then parts of one broken bone have the chance of showing up multiple times in the NISP. By taking into account duplication of the portions of elements, the MNI is more conservative in this sense. Like Minimum Number of Elements (MNE, see below), MNI is an ordinal-scale measure.

MNI is highly affected by how the sample is aggregated. In the case of Mantle, for the smaller taxa it is unlikely that bones from the same individual animal would have been distributed among multiple refuse contexts or houses. For larger animals or animals used during feasting, sharing of the carcass is much more likely. Different aggregation units are appropriate for different taxa, but these can be difficult to define. Therefore, in this case the minimum distinction method is used (the assemblage is aggregated at the site level for all taxa).

### ***Minimum Number of Elements and Minimum Animal Units***

Minimum Number of Elements, which is simply defined as “the minimum number of skeletal elements necessary to account for the specimens under study” (Lyman 2008:218), was calculated for deer from whole longbone ends plus the most commonly occurring fragment of that end (anterior, posterior, medial, or lateral), both proximal and distal, and any shaft fragments that could not be accommodated by the bone ends. For non-longbone elements, complete and almost complete items were counted and the number of fragments that would form additional individuals was estimated. In theory, this method should help to circumvent problems associated with counting overlapping skeletal parts. These values have been adjusted by the number of times the element shows up in the body in order to calculate Minimum Animal Units (MAU) (Binford 1984). The most numerous element is then used to norm the MAU.

### ***Species Richness***

As Lyman (2008:174) argues, calculating taxonomic richness (NTAXA) using different levels of identification is problematic because of overlap in categories. NTAXA is therefore calculated for unique taxa only. For example, Strigidae is counted as a taxon because no owls were identified below family, but Canidae and *Canis* sp. are not counted as taxa because both dog and wolf were identified within the genus *Canis*.

### ***Age at Death***

Relative (and in some cases approximate absolute) age at death was determined by tooth eruption and wear (see section on deer below), as well as the state of epiphyseal fusion of long bones (unfused, fusing with visible epiphyseal line [VEL], or fused). In addition, the presence of juvenile cortical bone was noted in the database to flag immature mammals and birds.

### 8.3 Taphonomy

Preservation was generally very good, and the collection includes fragile and small fish bones and taxa.

With the exception of some near-complete valves, much of the clamshell is very powdery. It seems that once the outer layer and the innermost layer of nacre are gone, the shell starts to fragment and disintegrate easily.

Only four fish scales were recovered, and one of these is from gar, which is quite robust. The lack of scales may point to: a preservation problem; the consumption of fish skins with the meat; or the skinning of fish at the catch location. Ictaluridae (catfish family) do not have scales. Champlain noted that all parts of the fish were consumed, although the appendages, scales and “inwards” were not to his personal taste (Crinnion 1998, citing Grant 1907: 315). Champlain visited in winter 1615–16, which suggests that he was describing fall-spawning fish or dried fish. Although there are some issues with Champlain’s descriptions of Huron diet and various translations of this text (Crinnion 1998), in this case we can be sure that he had first-hand experience with the consumption of scales and possibly fish heads.

As Stewart (1991b:21-22) noted for the Keffer site, fish can be over- and underestimated simultaneously. In general, fish bones break easily compared to those of birds and mammals, and there are many more bones in a fish skeleton than in a bird or mammal skeleton. On the other hand, they can be underestimated because of preservation issues and the likelihood that some bones were eaten with the flesh.

The surface of the mammal bone was well preserved, so that texture could be evaluated, but there is substantial evidence of carnivore chewing and digestion. Most of the longbones of mammals bigger than squirrel size have been broken, but generally only those of deer show true perimortem spiral fractures, which were likely the result of smashing the bone to extract the nutrient-rich marrow. Deer longbone ends may also have been crushed to extract bone grease.

Some of the bones and teeth showed signs of plough trauma, and others showed signs of more recent excavation trauma. This more recent damage generally did not hinder the identification process, especially once broken bones were refitted. As noted above, any bones that join on recent breaks are counted as NISP = 1 in the database to mitigate against interdependency. The recovered bone represents an unknown proportion of what was deposited originally, especially since the site was extensively plough-disturbed.

As is typical on Iroquoian sites, many of the specimens show signs of heat alteration. Of the 34% (n=12,900) that are heat altered, 40% are charred and 60% are calcined, the latter indicating higher heat. Charring is defined as a blackening of the bone, whereas calcination is defined as a white or blue discoloration of the bone (Lyman 2008). There is some overlap between these states, and some bones exhibited both states (in which case they are described as calcined).

A small proportion of the items show rodent gnawing. Some of the bones have been chewed by carnivores (<1%, n=304) or etched by digestive acids (4%, n=1309). Given the species identified at the site, this is most likely the result of the presence of domestic dogs. The digestion process causes pitting, smoothing and polishing of the bone (Lyman 1994:210-212) and would obliterate most traces of chewing, so the chewed number is therefore likely an underrepresentation. Some bone probably completely disappeared, and other specimens would be rendered unrecognizable by carnivore chewing, especially those of smaller mammals (Payne and Munson 1985). There are also indications that dogs were chewing crania and mandibles. This means it is possible that crania and mandibles of young animals were destroyed beyond recognition (Munson 2000).

Very few of the bones were both carnivore-gnawed and burnt, although at least some of the gnawing and chewing marks would remain visible after burning. This suggests burning was done during or immediately after preparation of the meal, before dogs had access to the refuse.

When cooking meat or fish, the Wendat placed heated stones into water in a kettle until the water was heated “and so cooked the meat to some extent” (Wrong 1939:109). Sagard seems to imply that this process was insufficient to completely cook the meat (Crinnion 1998). This kind of cooking process would not result in any burnt bone; only cooking above an open fire would. Even then, only exposed bone ends or breakage points would get burnt. It therefore seems likely that at least some of the Mantle bone was intentionally burnt, perhaps to deal with odours. It was predicted that more burnt bone would be recovered from the trench rather than the more distant Midden 1, but this was not the case (Table 62). Midden 1, the trench, and the features combined have similar overall percentages of heat (33–35%) and carnivore (3–6%) alterations. The percentage of gnawed bone is similar throughout, while there is some variation in the percentage that is digested.

The percentages of charred and calcined bones vary, with the refuse-filled trench and the features having a higher percentage of calcined bones. Since charring and calcination are part of a continuum of thermal alteration, small percentage differences may not be very meaningful. This large difference in percentages suggests that the bone destined for disused features and the trench was heated to a higher temperature. This may be for one or both of the following reasons: bone waste that was to be disposed of closest to the houses was more systematically burnt; or there was more systematic burning of bone waste during the latest phase of the village, when the trench was in use.

Table 63 shows the amount of heat alteration according to zoological class. In this case, heat alteration is positively correlated with reduced identifiability. The burnt fish bones are almost exclusively vertebrae, and these are usually still identifiable. For birds and mammals, most heat-altered bone can only be classified according to class. Overall, 97% of the burnt bone could not be classified to a taxonomic level below class.

It is an accepted fact that an intact fish bone from a site represents much less adhering meat than a deer bone. Due to the different impacts of taphonomic processes on the different classes, any discussion of relative abundance is here limited to within-class. In order to facilitate comparison of class contributions with other sites, the percentage of the total amount of bone represented by each class is provided, but this should not be used as an indicator of the different dietary contribution of those classes (Table 64).

Even with the excellent overall preservation, it is probably unwise to assume that element representation accurately reflects what was deposited in the ground. The estimated number of animals whose remains have been recovered based on MNI is only a fraction of the number of animals that must have been consumed, even if the diet consisted largely of maize.

### 8.3.1 Overview by Taxon

Sixty-seven unique taxa could be identified. Mammal bones are by far the most numerous remains, making up 87% of the assemblage (Appendix M). Fish comprise 6%, birds comprise 2%, and all other classes make up 1% or less of the total of 37,542 specimens. Overall, only 16% could be classified below the taxonomic level of class. The percentage within each class that could be identified below class varies. It is not unusual for fragments of shells, turtle shell, and frog or toad to go unidentified below class. The percentage of fish that could be identified below class is 54%, but that is because this includes the large numbers of Salmonidae vertebrae, which are quite distinctive. The percentage for bird and mammal is quite similar (81% and 87%, respectively).

### 8.3.2 Malacostraca

One burnt and one unaltered piece of a crayfish (family Cambaridae) claw was recovered (Cat. #952, Midden 1). Its survival would suggest that the soil acidity in that part of the midden is low.

### 8.3.3 Bivalvia

The clamshell is consistent in both relative thickness and appearance with locally available freshwater taxa. Only a few items were tentatively classified to genus or species level. These include: *Elliptio* sp., spike or eastern elliptio (n=18); *Proptera alata*, pink heelsplitter (n=1); and *Lampsillis* sp., lampmussel (n=5). *E. complanata* prefers the shallow water of permanent lakes and rivers and medium-sized streams. It is only known host is the yellow perch. *E. dillatata* prefers rivers and lakes. *P. alata* lives in large rivers and lakes with a mud bottom. It is only known host is the freshwater drum. *L. radiata* also lives in rivers and lakes, and *L. ventricosa* prefers rivers and occasionally lakes. Hosts for these latter two species are various sunfishes and perch (Clarke 1981:267, 268, 343, 347).

### 8.3.4 Gastropoda

Both thin-shelled and thicker-shelled snails were recovered. Most of the thin-shelled specimens are probably terrestrial, while the slightly thicker-shelled ones are likely aquatic. Since some of the snail shells were modified, a reconsideration of the thin-shelled, mainly flat, terrestrial ones that are usually deemed intrusive to the archaeological deposits may be necessary, as it is possible that they were collected and curated.

The worked snail from Feature 1146 cannot be definitively classified, while the four from the midden deposits were tentatively identified as *Pomatiopsis lapidaria* (river-bank looping snail, from Midden 1 [n=1] and midden-like concentration #2 [n=2]) and *Pleurocera acuta* (flat-sided horn snail, from midden-like concentration #3 [n=1]). *Pomatiopsis lapidaria* has flatly rounded whorls. This amphibious mollusc is rare today in Ontario, and is found on the banks of the Sydenham, Thames, and Ottawa River. *Pleurocera acuta* has flat-sided whorls and is common today in Ontario, inhabiting quiet areas of large streams and lakes (Clarke 1981:75, 83).

### 8.3.5 Actinopterygii

Bony fish make up 6% of the NISP. Almost 55% of the fish could be classified to a taxonomic level below class, and 47% to could be classified to family or lower. The site yielded 20 unique fish taxa (Figures 65-66). A number of different fish habitats would have been available within a day's travel of the site.

*“Currently, Duffins Creek contains 380 kilometres of watercourses. They...are dominated by cold water aquatic communities... Based on the database of fish collections at the Royal Ontario Museum’s Ichthyology Department, there have been 45 riverine species of fish found in the Duffins watershed...The lower Duffins Creek is a natural warmwater reach...The lower Duffins and associated marsh provide good habitat for a number of warmwater species such as smallmouth bass, northern pike and pumpkinseed.”*

*(Toronto and Region Conservation Authority 2002:3-4)*

The distance to Lake Ontario by canoe would be about 40 km. Fishing activity may not have been restricted to the closest body of water. There is also the Rouge River watershed to the west, Oshawa Creek to the east, Lake Simcoe to the north and Lake Ontario to the south, which may well have been a major source of fish and other aquatic animals. Great Lakes coastal wetlands and estuaries have high fish productivity, related to their high primary production, diverse habitats, and the rejuvenating effects of natural lake level fluctuations (Jude and Papas 1992).

Ten of the taxa known today or historically from Duffins Creek were also identified in the archaeological assemblage, namely: Atlantic salmon (*Salmo salar*); white sucker (*Catostomus commersoni*); brown bullhead (*Ameiurus nebulosus*); channel catfish (*Ictalurus punctatus*); American eel (*Anguilla rostrata*); rock bass (*Ambloplites rupestris*); pumpkinseed (*Lepomis gibbosus*); smallmouth bass (*Micropterus*

Figure 65: Fish identifications, NISP

Figure 66: Fish identifications, MNI

### ***Lepisosteidae***

One gar scale was identified. Given current distributions, this is likely longnose gar (*Lepisosteus osseus*). This piscivorous fish lives in warm lakes and slow-moving, vegetated streams (Scott and Crossman 1973:108). Gar scales are extremely robust, so it is interesting to note that we usually find only a few on each site. These sporadic scales could potentially have been curated.

### ***Amiidae***

Two cranial bones of bowfin (*Amia calva*) were identified. The adults of this piscivorous species live in “swampy, vegetated bays of warm lakes and rivers” and can be speared or caught by angling (Scott and Crossman 1973:14-15).

### ***Salmonidae***

Fish in the family Salmonidae were identified mainly from their vertebrae, which comprise about 50% of the identified fish remains. As has been shown by several researchers, the presence of Salmonidae can go largely unrecognized in an assemblage if only the fish cranial bones are identified below class, since Salmonidae cranial bones are relative less frequently recovered in relation to vertebrae than are cranial bones of some other taxa (Cooper 1996; Needs-Howarth 1999; Thomas 1996a).

The lack of Salmonidae cranial bone probably relates to their fragile and oily nature, which makes them less likely to preserve archaeologically (Lubinski 1996). X-ray absorptiometry on chinook salmon (*Oncorhynchus tshawytscha*) cranial bones shows that they ossify less densely than vertebrae, with the exception of dentary, angular, and maxilla bones (Butler and Chatters 1994). It is suspected the same pertains to Atlantic salmon (*Salmo salar*) bones. The cleaned bones of brook and lake trout (*Salvelinus* sp.) look and feel like cisco and whitefish (*Coregonus* sp.) in terms of their robusticity, but *Salmo salar* generally feels more papery and frail. The robust, toothed dentary should survive, but since the bone counts are so low, its absence may not necessarily imply off-site processing for Atlantic salmon and the presence of whole fish for the other two taxa. No brook trout were positively identified, although they may be present among the small numbers of unidentified Salmonidae vertebrae.

The relative lack of Salmonidae cranial bone may also be a function of off-site processing, whereby the heads were removed and (part of) the vertebral column was left in the dried or smoked fish (Stewart and Gifford-Gonzales 1994), as described by Sagard for the Huron (Wrong 1939:185-186). As noted by Williamson and colleagues (2003) for the 14th century Moatfield site on the Don River, when people are catching substantial numbers of fish in fishing camps located far away from the village, they may process and dry (or smoke) the fish at the camps for ease of transportation. Salmonidae are amenable to smoking because of their high fat content. The possibility that spawning fish were preserved for later consumption means that vertebrae may not enter the archaeological deposits for weeks or months (Thomas et al. 1998).

The presence of some cranial bone suggests that at least some whole salmonids were transported to the site. Table 65 shows the ratio of cranial bones to vertebrae for salmonids, eel and Cypriniformes (the latter being the only other (groups of) taxa at the site with vertebrae that can be classified at least to the taxonomic level of order and that have a relatively large NISP). The ratios are dependent to some extent on the number of vertebrae in each taxon, which varies considerably (eel have over 100, Salmonidae have between 50 and 70, and Cypriniformes have between 30 and 50). Ratios are also dependent on absolute size: the posterior vertebrae of all but the largest of eels would likely fall through 5.6 mm mesh, while the trunk vertebrae of the smallest bullhead would be caught because of their robust transverse and spinous processes (Williamson et al. 2003). Robusticity and relative identifiability of cranial bones also has an effect. Only eight cranial bones are likely to be consistently identified among the families Salmonidae,

Esocidae, Catostomidae, Ictaluridae, Centrarchidae, and Percidae, even when fragmentary (Needs-Howarth 2001). These “diagnostic elements” are the articular, ceratohyal, cleithrum, dentary, hyomandibular, operculum, preoperculum, and quadrate.

**Table 65: Ratios of Cranial Bones to Vertebrae for Select Fishes**

		Cranial	Vertebral	NISP	MNI	Cranial: Vertebral Ratio	Vertebral Count <sup>1</sup>
Salmonidae		1	48	49		2%	
<i>Salmo salar</i>	Atlantic salmon	2	94	96	2	2%	58-61
<i>Salvelinus fontinalis</i>	brook trout	0	7	7	1	0%	58-62
<i>S. namaycush</i>	lake trout	4	55	59	4	7%	61-69
<i>S. salar/S. namaycush</i>	Atlantic salmon or lake trout	4	83	87	4	5%	
<i>Coregonus</i> sp.	cisco or lake whitefish	15	538	553	15	3%	
<i>Coregonus clupeaformis</i>	lake whitefish	0	1	1	1	0%	55-64
<i>A. rostrata</i>	American eel	3	17	20		15%	103-111
Cypriniformes		133	213	346		38%	34-48

<sup>1</sup> From Scott and Crossman (1973).

Landlocked *Salmo salar* (Atlantic salmon) became extinct in Lake Ontario in 1898. They typically spawned in the fall, but it was noted that “spawning migrations up tributary streams may occur anytime from spring to fall...[and] some males may remain in the river all winter” (Holm et al. 2009:283). After hatching, young salmon spent one or two years in the stream before going downstream to Lake Ontario. There they would spend another year or two before going back upstream to reproduce. These salmon could reach weights of up to 18 kg (Burrige and Haddrath 2006:9). The only documented record of Atlantic salmon from Duffins Creek is a salmon that returned to its hatchery stream from a 1940s restocking experiment (MacCrimmon 1950). Unfortunately, there are no pre-extinction records for landlocked salmon in the local river systems, but that 1940s record is an indication that salmon could survive in the creek conditions as they existed in the 1940s.

*Salvelinus fontinalis* (brook trout) was tentatively identified from vertebrae, and more may be present among the small numbers of unidentified Salmonidae vertebrae. This fish, which has an average length of 280 mm, spawns when water temperatures drop below 10°C. In southern Ontario, it inhabits the upper reaches of coldwater tributaries (Holm et al. 2009:289).

The much bigger *Salvelinus namaycush* (lake trout), with an average length of 445 mm, is mostly found in lakes, although “it is known to migrate into some Great Lakes tributaries in fall” (Holm et al. 2009:299). It spawns in lakes in rocky areas as deep as 10 m or more once the water temperature goes down to 11°C. “It is rarely found in streams, although it is known to migrate into some Great Lakes tributaries in the fall” (Holm et al. 2009:298-299).

Lake trout occur in surface waters immediately after the melt (Scott and Crossman 1973:225), and they can be caught through the ice by angling (MacCrimmon and Skobe 1970:32). In autumn they move to near-shore locations (MacCrimmon 1958).

It is somewhat frustrating that *Salmo salar* and *Salvelinus namaycush* can be difficult to differentiate on the basis of their vertebrae. Because of the differences in their spawning timing and habitat, and the implications this has for human exploitation strategies, it would be useful to be able to identify all of their

vertebrae to species. Unfortunately, some vertebrae were not sufficiently similar to either lake trout or Atlantic salmon to identify them to species, but they clearly were not any of the other salmonids. A taxonomic category of *Salmo salar/Salvelinus namaycush* was created so that they could at least be distinguished from the smaller brook trout and *Coregonus*.

The Great Lakes used to have as many as eight species of *Coregonus* (Holm et al. 2009:284). Today only *C. artedii* (cisco) and *C. clupeaformis* (lake whitefish) are present. Before the collapse of the stocks from overfishing, annual catches of *Coregonus* totalled 10 million kg (Holm et al. 2009:294). The eight species are under 300 mm in average length, with the outliers being *C. artedii* (250 mm on average) and *C. clupeaformis* (381 mm on average) (Scott and Crossman 1973:233, 269). The only species-level identifications at Mantle are to *C. clupeaformis*. Given the size of the vertebrae, these are also likely mostly *C. clupeaformis* rather than the much smaller cisco species. Whitefish inhabit deep, cold lakes in summer, and they spawn at night in November in lake shallows, where they can be caught by gill or seine net technology. In early spring they can also be found in shoal waters, but they do not aggregate in spring the way that they do in the fall (Scott and Crossman 1973:272).

Lake trout, lake herring and lake whitefish spend most of their time in the pelagic zones of lakes, where they often concentrate in large numbers or in known zones. In spring and early summer they move below the thermocline, where they remain until the upper waters cool. The most efficient and predictable time to catch all these species is during spawning time in October, when they concentrate in large numbers in shallower waters (MacCrimmon and Skobe 1970:50, 54; Scott and Crossman 1973:239) and are accessible using canoes and gill-nets or spears. It is unlikely that resources would have been allocated to the lake fishery during the highly productive spring spawning run of the suckers and perch (Needs-Howarth and Thomas 1998).

### ***Esocidae***

Very few bones were identified as pike (*Esox lucius*) or muskellunge (*E. masquinongy*) (only three cranial bones, including two of the toothed dentaries from two different individuals, and six vertebrae were identified). The vertebrae of the large pikes are readily identifiable, and some of their cranial bones are very robust, so this absence may be real rather than the product of taphonomic factors. Pike tend to like “clear, warm, slow, meandering, heavily vegetated rivers or warm, weedy bays of lakes” (Scott and Crossman 1973:360). Smaller pike are more tolerant of low oxygen concentrations than larger pike, and they prefer shallower water with more dense vegetation (10 cm depth for every 12 mm of body length) (Casselman 1996). There are records of very large pike being taken in Lake Simcoe at 9 metres (MacCrimmon and Skobe 1970). Pike spawn in shallow water on river floodplains and marshes immediately after the ice melts in spring. As noted by Williamson and colleagues (2003), as late as the mid-nineteenth century, people would set nets near the mouth of the Don River to catch spawning pike. Sagard mentions that the Huron caught pike incidentally when fishing for salmonids in fall (Wrong 1939:230).

### ***Gadidae***

Only one bone, a vertebra, was identified as burbot (*Lota lota*). This fish “prefers the cold bottom waters of lakes, but may occasionally been found in cold streams” (Holm et al. 2009:316). It may have been a by-catch of the fall lake fishery. Today, it “is frequently caught by angler’s ice-fishing for Lake Trout” (Holm et al. 2009:316). Burbot was likely prized for its oily liver (Fox 2000).

### ***Catostomidae***

The cypriniform identifications pertain mostly to vertebrae that could be identified as either Catostomidae or Ictaluridae if a more detailed level of analysis had been pursued. A lot of the Catostomidae identifications are made based on vertebrae. Since the only positively identified species from the Catostomidae family are longnose (*Catostomus catostomus*) and white sucker (*C. commersoni*), it is likely that all those family-level identifications are for those two species, rather than for *Moxostoma* sp. (the redhorse suckers), which is the other genus that occurs in the Lake Ontario–St. Lawrence drainage. Like Mantle, the Moatfield and Keffer sites, which also have large samples, did not have *Moxostoma* either (Stewart 1991b; Williamson et al. 2003). Problems in differentiating between many skeletal elements of the two species are reflected in the high proportion of genus-level identifications. Catostomidae account for 16% of the below-class identifications.

Today, *C. commersoni* is much more frequently encountered on the north shore of Lake Ontario than *C. catostomus* (Mandrak and Crossman 1992:75-76). In southern Ontario, the longnose sucker is found mostly in lakes, except during its spring spawning run into tributaries. Both species of *Catostomus* prefer cool, shallow waters and often spawn in the same streams, the longnose spawning a few days before the white (Holm et al. 2009:222). Older white suckers occupy deeper waters further from shore (Scott and Crossman 1973:542). During spawning, suckers are easily speared (Cleland 1982:774).

### ***Ictaluridae***

Two bones were identified as channel catfish (*Ictalurus punctatus*), and another two were tentatively identified as brown bullhead (*Ameiurus nebulosus*). The 44 *Ameiurus* sp. identifications were all very similar to brown bullhead, but because the reference collection does not contain the other two possible species (*A. melas* and *A. natalis*), the latter of which is known from Duffins Creek, the identification was left at the genus level. An additional 43 bones (many of them vertebrae) were identified as catfish family, and could conceivably include stonecat (*Noturus flavus*), which is known from Duffins Creek today. The MNI calculations for catfish and bullhead exclude modified pectoral and dorsal spines, since these may have been curated from a previous site location, and may not represent food refuse that is contemporaneous with the Mantle occupation.

Brown bullhead inhabit ponds and lake margins as well as the slow moving, vegetated parts of rivers with sandy or muddy bottoms (Scott and Crossman 1973:602). Given their nocturnal feeding habits and generally solitary nature, they are most efficiently caught using passive technology such as traps. Channel catfish live in lakes and moderate to large rivers (Scott and Crossman 1973:608). Neither the channel catfish nor the bullheads are noted for spawning run migrations (Scott and Crossman 1973:593, 579, 601). As with the large Salmonidae, it is unfortunate, because of the missed potential for inferring behaviour and habitat, that it was not possible to definitively classify about half of the Ictaluridae. As noted by Stewart (1991b:14) and Courtemanche (2003), the flesh of members of the catfish family can be smoked, but, because of the small size of some of them and their close proximity to the village, there may not have been an impetus to do so.

### ***Cyprinidae***

One very small cyprinid pharyngeal arch (#12241, Feature 969) may represent stomach contents of a piscivorous fish.

### **Anguillidae**

Twenty bones of American eel (*Anguilla rostrata*) were identified, including fragments of three cranial bones and 17 vertebrae. Feature 360 contained eight of these vertebrae as well as two cranial bones. Since eel cranial bones are very fragile and the caudal vertebrae are small enough to fall through 5.6 mm mesh, eel may be underrepresented in the assemblage. Like fall-spawning Salmonidae, eel are a cold-water resource that aggregate during their spawning run and can be stored after smoking. Since eel spawn at sea, though, the only easy and predictable way to intercept spawn-run populations would be by fishing on the St. Lawrence River. The fish at Mantle likely represent immature individuals that were perhaps caught more incidentally. Eel like substrates of gravel, sand, and silt (Hosley 1956:115). Distribution records for Duffins Creek suggest that catching eels would have necessitated a trip to the mouth of the creek at Lake Ontario (Toronto and Region Conservation Authority 2002). It is therefore possible that all these taxa were caught during the same fishing expeditions. Following Williamson et al. (2003), eel is considered to be related to the fall lake fishery.

### **Centrarchidae**

Perciform fishes other than larger walleye or sauger (*Sander* sp.) are likely underrepresented in the NISP because their vertebrae are less distinctive than those of the other orders of fish. They are therefore much more likely to end up in the unidentified fish component, and the caudal vertebrae of smaller taxa and individuals would fall straight through the dry screen mesh.

*Centrarchidae* (sunfish family) do not tend to engage in extensive spawning runs (Scott and Crossman 1973:589-603, 703-706, 716-717). Exploitation may have coincided with their summer spawning time but may not have been aimed specifically at spawning-run exploitation (Needs-Howarth and Thomas 1998; Needs-Howarth 1999). All four sunfish known from Duffins Creek were identified at Mantle: rock bass (*Ambloplites rupestris*); pumpkinseed (*Lepomis gibbosus*); smallmouth bass (*Micropterus dolomieu*); and largemouth bass (*Micropterus salmoides*). Other north shore species are bluegill (*Lepomis macrochirus*) and, more rarely, green sunfish (*Lepomis cyanellus*) and longear sunfish (*Lepomis magalotis*) (Mandrak and Crossman 1992:135-140). Since the various species of *Lepomis* hybridize to produce fertile offspring and since the reference collection contains only *Lepomis gibbosus*, identifications are limited to the genus level. The behaviour of the two main species is quite similar (Scott and Crossman 1973:716-717, 720-723), which simplifies interpretation. Pumpkinseed today often dominate small bodies of warm water (Scott and Crossman 1973:716). Williamson et al. (2003) have suggested that *Lepomis* at the Moatfield site may have been caught in traps.

### **Percidae**

Yellow perch (*Perca flavescens*) inhabit a variety of waters, including shallow, open, clear water (either warmer or cooler) with moderate vegetation found in large lakes, ponds, and quiet stretches of rivers. Yellow perch have extensive spawning runs into rivers and small streams in late April and May (MacCrimmon and Skobe 1970:101), where they can be caught using seine nets (Scott and Crossman 1973:759) or weirs. They can be angled, but this is not as efficient as passive technology. Williamson et al. suggest that a basket trap or pound net positioned to catch bullhead would also catch some perch (2003). Traps intended for bullheads and suckers may have also caught some perch.

The availability of yellow perch is not as strictly related to spawning season as it is for salmonids or suckers because, as noted by Stewart (1991b:17), perch inhabit fairly shallow water (less than 10 m deep), swim in loose schools, and feed year-round (Scott and Crossman 1973:759). Perch were probably also an important part of the warm-weather fishery (Needs-Howarth and Thomas 1998). Yellow perch bones (n=32) are more numerous than all the sunfishes combined. It is not easy to compare them with non-perciform fish because of the lack of vertebral identifications within the order Perciformes.

Nine walleye or sauger bones (*Sander* sp.) were identified, including two quadrates and seven vertebrae (MNI=1), suggesting that whole fish were brought back to the site. Walleye live at moderate depth in cool, large, turbid lakes, large streams, or rivers. Walleye sometimes school with white sucker and often associate with yellow perch, northern pike, muskellunge and smallmouth bass (Scott and Crossman 1973:772).

### Sciaenidae

Freshwater drum (*Aplodinotus grunniens*) is represented by a single pharyngeal arch. This is a particularly robust element, and maybe also have been curated by an inhabitant of the Mantle village because it has an interesting feel. This fish likes the cool to warm waters of lakes and large, slow-moving streams, and spawns in summer (Holm et al. 2009:425).

### 8.3.6 Amphibia

The 167 amphibian remains make up less than 1% of the NISP. The toad elements from Midden 3 are most similar to Woodhouse's toad (*Anaxyrus woodhousii*), which is now restricted mostly to the north shore of Lake Erie (Conant 1958). A number of largely complete frog or toad skeletons were labelled recent/intrusive and are not included in the NISP. However, some of the frog or toad remains that are included in Appendix N may also be intrusive. Both frogs and toads are a gathered spring and summer resource.

### 8.3.7 Reptilia

The 174 reptilian remains also constitute less than 1% of the NISP. Most of the turtle remains (n=127) could not be classified to genus or species level. The snapping turtle (*Chelydra serpentina*) accounts for five elements, and the painted turtle (*Chrysemis picta*) for 33. Some of the carapace and plastron fragments and portions showed signs of polish from use. One marginal carapace portion (Cat. #9148, Feature 1238) has been drilled, and the vertebrae of another carapace have been ground away (Post 16, 515-190). These artifacts may have been curated for some time and may not represent dietary items contemporaneous with the site. The snapping turtle remains and the unidentified turtle remains included bones from the pelvic girdle and appendicular skeleton, suggesting at least some of them were brought to the site whole and were probably eaten. The habitat preference of painted turtles is similar to that of young pike, sunfish, and especially bullhead (Williamson et al. 2003), and they could have been caught in traps positioned to catch bullheads. As Stewart notes, turtle eggs "may have been an interesting dietary supplement" (1991b:59). Of interest is the fact that 16% of the reptilian remains (mostly turtle carapace and plastron) are heat altered, suggesting turtles were sometimes roasted in their shell (Table 64).

There were also nine snake vertebrae from a variety of contexts, which may represent hibernation deaths. Three different subfamilies within the family Colubridae are represented, namely, Colubrinae (corn snakes, fox snakes, rat snakes); Natricinae (garter snakes); and Xenodontinae (hognosed snakes). Members of all three of these subfamilies of non-venomous colubrid snakes occur in Ontario (<http://nhic.mnr.gov.on.ca/herps/snakes.html>).

### 8.3.8 Aves

The 817 bird remains from Mantle represent 14 unique taxa and comprise 2% of NISP. Less than 20% of the bird remains could be classified to a taxonomic level below class. This is probably because a relatively high proportion of the bone was worked (14%). By way of comparison, only 3% of mammal bone was worked. Bird bone beads can be hard to identify beyond size class, and if these beads arrived at

the site from an earlier village, the longbone end waste material that might have been useful for identification is missing. Many of the individual bird taxa represent just 1% or less of the total number of bird bones (Figure 67-68).

Aboriginal people hunted birds with bows and arrows and with nets. Like mammals, birds had value beyond simply food (which probably also included their eggs). Iroquoian people frequently made beads from the long, straight wing bones of Canada goose, turkey, and sandhill crane. Some species, like colourful woodpeckers, may have been caught for their feathers, but raven and bald eagle would have likewise been collected for ideological reasons (Tooker 1969).

Figure 67: Aves identifications, NISP

Figure 68: Aves identifications, MNI

### ***Migratory waterfowl***

The common loon (*Gavia immer*) was represented at the site by a distal radius fragment (#1492, Midden 1). This animal could be caught with gillnets (Williamson et al. 2003:75, citing a personal communication by John Casselman). Common loons breed in the area, and they may very occasionally have wintered in the Toronto area (Cadman 1987:36-37; Godfrey 1986:22). They were probably more common when human population densities were much lower.

The tentative identification of the distal ulna of a swan (cf. *Cygnus* sp.) (#9398, trench feature 709), is likely a male tundra swan (*C. columbianus*) or female trumpeter swan (*C. buccinator*), based on morphology and size, indicating a spring or fall catch. Trumpeter swan “formerly occurred sparingly in migration in southern Ontario,” including on Long Point on Lake Erie and in the Toronto area (Godfrey 1986:73). Tundra swans stop on their spring migration at Long Point (Godfrey 1986:73).

Given that no domestic goose was identified in the later, historic portion of the sample, the 12 Anserinae identified are probably from Canada goose (*Branta canadensis*), which did not typically winter or breed in the area (Godfrey 1986:80). All of the duck material was fragmentary and none of it could be identified below family.

### **Birds of prey**

At least three species of raptor were identified: red-shouldered or red-tailed hawk (*Buteo* sp., Cat. #6317, Cat. #3618, both likely from the same individual, Feature 368); bald eagle (*Haliaeetus leucocephalus*, Cat. #755, Midden 1; Cat. #8036, Feature 744); and northern goshawk (*Accipiter gentilis*, Cat. #9557, Feature 709 trench). In addition, one fragment was identified as *Accipiter* or *Buteo* sp., and was a good size match for *B. jamaicensis* (Cat. #2857, 345-170, Post 82). The goshawk element was a coracoid, and the rest of the raptor remains are all from the distal hind limb (tibiotarsus, tarsometatarsus, distal phalanx) and may represent curated raptor feet. The area north of Toronto is now at the southernmost limit of the breeding range for goshawk. They prefer forests and woodlands as well as forest edges and clearings, and they winter south of their breeding range (Godfrey 1986:139). Both red-tailed hawk and red-shouldered hawk breed in the area and throughout southern Ontario, and they inhabit both woodland and open country (Godfrey 1986:139). Bald eagles are usually found in the vicinity of larger rivers and lakes and the adjacent countryside. They also breed in the area, and southern Canada is part of their winter range (Godfrey 1986:127).

The two Strigidae identifications (Cat. #5409, Midden 2, proximal phalanx; Cat. # 6016, Feature 159, ulna fashioned into a bead) both match the size of great horned owl (*Bubo virginianus*), which breeds in Ontario in a range of wooded environments, including heavy forest and isolated groves (Godfrey 1986:310).

### **Upland game birds**

The upland game birds identified are: spruce grouse or ruffed grouse (*Dendragapus canadensis*/*Bonasa umbellus*, n=8); ruffed grouse (*Bonasa umbellus*, n=13); turkey (*Meleagris gallopavo*, n=16); and passenger pigeon (*Ectopistes migratorius*, n=66). These comprise 13% of the bird remains and 67% of the identified bird specimens. Most of the family-level grouse remains closely resembled ruffed grouse. The breeding range of spruce grouse formerly included Peel county (Godfrey 1986:156), but none were positively identified. As its common name suggests, spruce grouse is an inhabitant of coniferous forests, and must therefore be treated separately from ruffed grouse in terms of habitat preference. Turkey and pigeon may have been field pests.

Grouse and turkey are year-round residents of southern Ontario. Ruffed grouse prefer secondary growth deciduous and mixed woodland edges and openings, while turkeys like “extensive mature deciduous forest” (Godfrey 1986:165) and they associate in flocks. Stewart (1991b:45) argues that turkeys may have been easiest to catch when deep or soft snow on the ground forced them to spend time in trees, although their weight would not be quite as optimal as in fall.

Passenger pigeons arrived in spring, stayed through the summer, and then left again in fall. Passenger pigeon remains are ubiquitous on Iroquoian sites. Now extinct, they were at one point so numerous that

one in four birds in North America was a passenger pigeon. They nested in the lower Great Lakes in great numbers, migrating south for the winter. The hunt for adult passenger pigeon could have occurred during the spring or fall migration, or in a nesting colony in an oak or beech forest. Their “largest nesting colonies occupied hundreds of square miles” (Godfrey 1986:302).

### ***Crow and Raven***

A Corvidae tibiotarsus was tentatively identified as common raven (*Corvus corax*) (Midden 1, #1491). This specimen could represent a very large crow or a raven obtained through trade. The other Corvidae remains at Mantle (Midden 1 and midden-like concentration #3) were positively identified as American crow (*C. brachyrhynchos*). The ulna and tarsometatarsus may have been part of a curated wing or foot, respectively. The humerus and femur may not be curated elements. Crows breed in the area of the Mantle site (Godfrey 1986:395), while the breeding range of ravens is far north of the site, starting in the Canadian Shield (Cadman 1987:290-291). Ravens winter “mainly within breeding range... [and] rarely [in] extreme southern Ontario” (Godfrey 1986:397).

### ***Picidae***

The Picidae identifications (Feature 55 trench, Cat. #568, Cat. #757, Cat. #1044) all represent smaller woodpeckers, either northern flicker or yellow-bellied sapsucker size, both of which breed in the area (Cadman, 1987:236-237, 246-247). All four are ulnae, suggesting that these elements may have been curated for the attached flight feathers. Those of the northern flicker are bright yellow underneath.

## **8.3.9 Mammalia**

The mammal portion of the Mantle zooarchaeological assemblage contains 23 unique taxa. It is dominated by deer in terms of NISP, MNI (Figures 69-70), and (intuitively) estimated meat yield. The percentage of unidentified remains is relatively high for mammals, as 85% could not be classified below the taxonomic level of class. In order to improve the information yield of these unidentified mammal remains, they were labelled with an approximate size class based on overall item size, thickness, and circumference. While a bone labelled “squirrel-size” definitely came from a smaller animal than one labelled “deer to moose size,” there may be some overlap between adjacent categories of similar-sized animals.

Figure 69: Mammalian identifications, NISP

Figure 70: Mammalian identifications, MNI

### **Garden-Hunted Taxa**

The Iroquoian local agricultural system focused on swidden root and tree cropping supported by “garden hunting” and fishing, and functioned according to the predictions articulated by Linares (1976). In a hunter-gatherer context, squirrels and woodchuck would be fairly costly and difficult to exploit since they are too small to effectively hunt with bow and arrow and they offer little return relative to energy expenditure. In the context of Iroquoian villages, though, small terrestrial rodents likely surreptitiously fed on corn planted by the inhabitants, thus simultaneously becoming a threat to the crop and a relatively easily accessible food source (Thomas et al. 1998).

*“Agricultural land clearance, crop cultivation, and related environmental changes – including village construction, accumulation of agricultural surpluses and large scale refuse disposal – creates habitat which can support certain mammal species in higher densities than might otherwise exist in a pristine forest environment. These species are able to survive and prosper in close proximity to a human settlement due to high reproductive rate, relatively small body size, other adaptive abilities.”* (Williamson et al. 2003:77)

Thomas includes the following species in Ontario in the category “garden-hunted”: snowshoe hare (*Lepus americanus*); eastern cottontail (*Sylvilagus floridanus*); grey squirrel (*Sciurus carolinensis*); red squirrel (*Tamiasciurus hudsonicus*); chipmunk (*Tamias striatus*); woodchuck (*Marmota monax*); and possibly raccoon (*Procyon lotor*) (1996b:151). All of these species also have pelts that may have been desired.

Snowshoe hares are active year-round at dusk and at night (Banfield 1981). They inhabit forests, swamps, and riverside thickets (Banfield, 1981:80-83). In the southern part of their range, including Ontario, they can be found in cedar or spruce swamps (Peterson 1966).

Woodchucks like corn (Banfield 1981:108), so can be a garden pests. They hibernate, and they therefore would only have been available from April to October (Banfield 1981:108). Stewart (1991b:31) argues that the best time to catch woodchuck would be just before they go into hibernation (in the fall) as they would be heaviest at this point. The habits and food preferences of the woodchuck (fresh green vegetation) would have attracted them to the fields, for both the crops themselves and for the weeds growing amongst the crops. Their pelts are in poor condition when they emerge from hibernation (Banfield 1981:107), so, as a source of fur, woodchuck would be most desired later in the season.

Grey and red squirrels are active year-round in daylight hours, and their movement through the trees makes them easy to locate. Grey squirrels moult in early May to mid-June and again in late September to early November (Banfield 1981:133). Their propensity to live in large numbers in areas with abundant food (nuts, seeds, bugs, fungi, and birds' eggs) (Peterson 1966:108), their boldness with people, and their daylight activity period make them easy prey to locate (Stewart 1991b:37). The tree-dwelling red squirrels may have been desirable because of their coat, which is in peak condition in summer and winter (Banfield 1981:138-139).

The ground-dwelling chipmunk hibernates during the winter months. Their coat would have been in prime condition outside of the midsummer and late autumn or early winter moult (Peterson 1966:123). Although they usually prefer hardwood forests, they “will also inhabit more open country such as hedgerows, fences, stone piles and gardens, if the earth is porous enough for tunnelling and plenty of cover is available” (Banfield 1981:97). They frequently subsist on corn and sunflower seeds in cultivated areas.

Of the seven deer mouse or white-footed mouse (*Peromyscus* sp.) identifications, six are cranial and one, cf. identification, is a possible femur. Of the six meadow vole (*Microtus pennsylvanicus*) identifications, two are cranial. It is possible that these microtine rodents, which would certainly have been garden pests,

were eaten by the site's dogs (Sauks Burns 1979), or were roasted whole and eaten by humans, with the head likely removed to avoid the teeth.

The natural habitat of the raccoon is hardwood forests near streams or lake edges (Peterson 1966:226), but, given the scavenging habits of today's urban raccoons and their love of corn (Banfield 1981:314), they have been included in the garden-hunted category. Raccoons are in prime condition in fall, when they could be snared or trapped.

### ***Fur-bearers***

Fur-bearing species include beaver, muskrat, fox, black bear, raccoon, mink, marten, lynx, and bobcat. As noted above, woodchuck and squirrel may also have been hunted for their fur.

The 107 beaver (*Castor Canadensis*) bones make up 2% of the below-class mammal identifications. Beavers may have also been trapped for their pelts. Stewart has argued that they may also have been caught primarily for the incisors, "which provided valued raw material for tools" (1991b:29). Certainly, at many Iroquoian sites, the incisors far outnumber other parts of the body. For this reason, beaver incisors have been excluded from the MNI calculations. Beaver lodges are easy to spot and are used for multiple years, and beavers could be trapped under water near their lodge, caught while travelling on land to access new food sources, or caught as young animals set out to find new territory (which is also the case for muskrat). Their fur would be least desirable during the moult, which happens in late autumn and spring (Banfield 1981:158).

Muskrat (*Ondatra zibethicus*) meat may have been a useful lean-season resource (Thomas 1988). The seven muskrat specimens at Mantle could all have come from a single individual. Adult muskrat "appear to shed their fur more or less continuously throughout the year" and in autumn and spring their pelt takes on a blotched pattern (Banfield 1981:197-198). This means that muskrat pelts would be most attractive in either summer or winter. Due to their seasonal movements, summer and winter would also be the seasons in which they are easiest to locate (Stewart 1991b:32).

The two fox species present in Ontario in the sixteenth century are osteologically similar. Both red fox (*Vulpes vulpes*) (NISP 2) and the now-extirpated grey fox (*Urocyon cinereoargenteus*) (NISP 2) were positively identified. A further three elements could not be identified. The grey fox "prefers forests and marshes and is less at home in farm lands than the red fox" (Banfield 1981:303). Due to its nocturnal habits, the most effective way to catch a fox is by trapping. Red fox run when pursued, but grey fox are often treed (Peterson 1966).

Black bears (*Ursus americanus*) prefer heavily wooded areas, particularly in deciduous forests (Banfield 1981:306). They are most effectively and efficiently caught just before they go into hibernation in the late fall or early winter, when they are fat and sluggish from eating and their pelts are in prime condition.

The bear, deer, and fish that Iroquoian peoples were procuring may have occupied the same environments in the autumn (Stewart 1991b:40). Between AD 1600–1650, the historic Huron did not engage in systematic bear hunting because their wide ranges and low population densities would have entailed high search costs (Heidenreich 1971). Like many Iroquoian sites, Mantle has some, but not a large quantity of, bear remains, and the amount of remains determined to be acquired by hunting while the site was occupied is certainly diminished when the practice of curating bear teeth is taken into consideration. Pelts may also have been curated, and these often have phalanges still attached. It is difficult to distinguish these in the archaeological record as these same pelts may have been used to transport the animal's deboned meat to the village if the hunt took place far enough away to make weight a consideration.

Young bears were sometimes raised in an enclosure in the longhouse (Wrong 1939:220) and killed after two or three years for a feast. If the Mantle occupants, like the historic-period Wendat, kept bears in the village, the remains of their hides would still represent meat eaten by the occupants. There are some younger bear remains from Midden 1 (Cat. #1367 right mandible age 1.5 to two years; Cat. #1370 second mandibular premolar (likely from the same individual); and Cat. #4228 tibia) and from the units (#11724 left upper canine, 525-150). There are also definite adult elements (Cat. #4472 Midden 1 ulna shaft with pronounced muscle-attachment areas; Cat. #8830 Feature 1408 440-130 fifth metatarsal). The site-wide MNI for bear is three (NISP 85, or 2% of below taxonomic level of class mammal identifications). The MNE for crania and for the torso and limbs is two, and the MNE for the ankle and foot is three. The cranial MNE is the result of recovered canines, several of which show signs of curation, and may not represent animals killed at the same time that the site was occupied. Also, since bears may have been eaten in a ceremonial context and because they represent a large packet of meat, bones from one individual may be distributed in several refuse contexts.

Raccoons (*Procyon lotor*) are omnivorous, and corn “tops their palatability list” in agricultural regions (Banfield 1981:314). They may have been caught specifically for their lush fur, and are therefore also included under the fur-bearer category. Raccoons would also be in prime condition in terms of meat and pelts in fall. The 17 raccoon remains represent all parts of the body, including three bacula, which explains their proportionately high MNI. Given their prevalence, it is speculated that these bacula may have been curated. No other bacula were identified.

It is unlikely that Iroquoians would have eaten mink or marten on a regular basis as their meat would have been largely unpalatable. They were valued for their fur, as occasional skinning marks demonstrate (Cat. #1178 marten mandible from Midden 1). The 16 Mustellidae identifications came from: Midden 1; midden-like concentration #3; Features 354, 568, 1221, and 1250; Post 45 in 395-155; and Post 9 in 395-205. The marten (*Martes americana*) remains include cranial, longbone, and metapodial elements. The tentative fisher (*Martes pennanti*) remains include a cranium and phalanx. The mink (*Neovison vison*) remains are both humeri, as is the “Mustellidae mink to marten size” specimen. The nocturnal mink lives both in streams and on land (Banfield 1981:330).

The tentative otter (*Lontra canadensis*) identifications are both phalanges (from diagonally touching squares in midden-like concentration #2), and may have been attached to a pelt.

Lynx (*Lynx canadensis*) and bobcat (*Lynx rufus*) are similar osteologically, although they differ in their proportions. *Lynx* sp. is represented by two teeth and two left ulnae (Midden 1, midden-like concentration #2, the borrow trench, and Post 2 in unit 485-165), and the tentative bobcat is represented by a proximal phalanx (Midden 2, non-adjacent to the *Lynx* sp. square). While bobcat is more adaptable to agricultural lands (Banfield 1981:352), both these felids are nocturnal and solitary (Banfield 1981:349, 352), so would be difficult to procure except by trapping.

### **Canidea**

Coyote, or brush wolf (*Canis latrans*), was not present in Ontario until the early 1900s (Banfield 1981; Peterson 1966), so it is unlikely that any of the Mantle *Canis* sp. material is coyote.

DNA analysis on modern wolves has shown that the eastern wolf, whose historic distribution included the north shore of Lake Ontario, is a separate species from the gray wolf, rather than a subspecies (Wilson et al. 2000). DNA and morphometric analysis on *Canis* material excavated from the Lawson site (dating to around AD 1530) support this, suggesting that “the wolf that was historically present in the eastern temperate forests of southwestern Ontario was an eastern wolf (*C. lycaon*) that evolved in North America (New World), rather than a subspecies of gray wolf (*C. lupus*) that evolved in Eurasia” (Rutledge et al.

2010:1278), although the data did not exclude the possibility that wolf material from Lawson was of *C. lycaon* x *C. lupus* hybrids. In light of this DNA research, wolf remains in the database are marked *Canis* cf. *lycaon*, rather than *Canis* (cf.) *lupus*.

The site-wide MNI for dog (and specimens that are likely dog) is 11 based on mandibles and dentition. Only two of the 20 erupted and mostly-intact Canidae canines had not been worked. This element is therefore excluded from the corrected MNI. The size of dog breeds was not the research focus for this project, so relative size is noted only occasionally in the database. Qualitative observation of the remains indicates there was some size variation.

The two dog burials (530-165 trench 709; 445-220 Feature 1442) have been excluded from the analysis because their skeletal completeness in such a small volume of soil suggests that they are not likely to have been food refuse, and because, without further detailed study, it is not clear whether they are Iroquoian or historic Euro-Canadian. The burial in Feature 709 trench is bigger than a pup in the reference collection labelled 2–4 months, but none of its longbone epiphyses have fused. The burial in Feature 1441 possesses permanent molars, but the distal tibia and femur are still unfused, suggesting this animal was less than 13–16 months old (Silver 1969:286).

Five large *Canis* sp. identifications are almost certainly not dog based on size and/or morphology: a mandible (Cat. #4815) from midden-like concentration #2; a radius (Cat. #7331) from Feature 1490; two distal metapodia portions (Cat. #9660) from trench Feature 709; and a maxilla (Cat. #9217) from Feature 1250. Given the recent DNA research by Rutledge et al. (2010), these are likely *Canis lycaon* rather than *C. lupus*.

### ***Cervidae***

White-tailed deer (*Odocoileus virginianus*) and likely-deer bones account for 61% of the mammal bone classified to a taxonomic level below class (n=2654). In addition, there are confirmed remains of wapiti (n=67) and moose (n=1), as well as family-level identifications of “Cervidae deer/wapiti size” (n=112); “Cervidae wapiti/moose size” (n=26); and antler (probably mostly deer based on size and shape) (n=141). There are also Artiodactyla remains that could not be identified to family (n=209). Some of these identifications could be sheep, goat, or cow, but, given the NISP proportions, most are probably deer.

### ***White-tailed Deer***

The 2,654 deer bones present at the Mantle site provide an MNI of 30 when the aggregation unit is the site. This is likely an underestimation of both the number of individuals actually present and of the number of individuals that would have been brought into the village originally, but, since deer may have been shared among households, the site level is the most justifiable aggregation unit for MNI calculation.

Deer in the northeastern part of North America, the subspecies *O.v. borealis*, have very predictable behaviour. For most of the year, they are solitary or are found in small groups. In winter, however, they may congregate (“yard”) in areas like white cedar swamps that provide shelter from storms, are free from deep snow, and have a supply of food (Severinghaus and Cheatum 1956:83, 139). These movements are not random, and deer migrate from their yarding area back to the same summer range (Tierson et al. 1985). Although they are technically in predictable locations year-round, in the Lake Simcoe area, for example, the summer dispersal area is about 10 times larger than the winter yarding area, and even larger if there is less than 100% forest cover (Broadfoot, et al. 1996). White-tailed deer (*Odocoileus virginianus*) prefer “an interspersed cover types, edges of hardwood forests, glades, swamp edges, banks of streams, and cedar swamps” (Banfield 1981:393). Deer will eat sumac, which is often found in abandoned fields and disturbed areas today.

All parts of the deer body are represented in the Mantle assemblage, although not in equal numbers (Figures 71-72). This is likely largely a function of post-depositional, environmental taphonomic processes rather than cultural factors such as differential transportation of body parts back to the site. As Burns (1979) notes for the Draper collection, the overrepresentation of deer lower limb bones in terms of NISP is not surprising because the phalanges are used and curated for “toggles,” and the metapodia are used to produce awls, needles, and projectile points. While the proximal and intermediate phalanges are used intact, the metapodia may be broken into several pieces, inflating the NISP count. Deer metapodia and proximal and intermediate phalanges “would have been retained regardless of where the carcass was initially butchered” (Thomas et al. 1998:95). At Mantle, phalanges were apparently less desired, or there were enough of them that some were regarded as surplus and were discarded without being worked. The distal phalanx shows up simply because it would be hard to discard it at the kill site without damaging the condyle of the intermediate phalanx. This is reflected in the high MNE for the distal phalanx, which is only rarely used for artifacts and has no adhering meat. It is also possible that people may have found an industrial purpose for the gelatine in the attached keratinous hoof coverings, although this cannot be confirmed.

Many of the phalanges were both pitted and smoothed, which is similar to those recovered from Keffer (Stewart 1991b:61). While many phalanges at Keffer have carnivore canine puncture marks, suggesting that the feet may have been considered appropriate “dog food” (Stewart 1991b:62), the phalanges at Mantle lack these marks, suggesting they were used differently.

There are 452 deer cranial elements, including 42 maxilla, 33 other cranial elements, 85 mandibles, 87 loose mandibular teeth, 131 loose maxillary teeth, and 72 loose unidentified teeth fragments. The third cusp of the mandibular third molar (M3) reaches its full height above the gum line starting at 20 to 24 months, whereas the deciduous premolars are replaced by permanent molars starting at 17 to 20 months (Severinghaus 1949:201). Element duplication of mandibular M3 and mandibular deciduous premolars (dP) can therefore be used to establish MNI. Taking into account only element duplication of non-contemporaneous teeth, the MNE for the cranium is 11 (eight mandibular M3 plus three for mandibular dP2). The dental data indicate that some fawns were being hunted, and the epiphyseal fusion data confirm that (one fusing proximal radius, indicating an animal around five to eight months).

Unshed antler indicates a fall or early winter kill (Banfield 1981:392). Antler gets denser over time, so antler collected in fall through to the time when it is shed would be most suitable for artifact manufacture. In fact, all of the antler identified from the site appeared dense to very dense. One cranium with part of the pedicle (Cat. #2107, Feature 475, 390-175) was found, and although it could not be positively identified as deer, it is of the right size. It is likely from a male, although females will sometimes carry antlers as well. One individual had not yet shed its antlers, and the antler had been removed by hacking. The use of a metal implement could not be ruled out with confidence, although Stewart (1991b: 65) describes a similar pedicle from Keffer, where the hacking could have been achieved with a stone implement like a stone axe. At Draper, there were also portions of deer frontal with adhering pedicle, which suggests that whole deer were being brought back to the site. In a sample of 929 deer from Draper, six had adhering pedicles (Burns 1979:143), which is a proportion much higher than at Mantle.

Figure 71: White-tailed Deer - MAU

Figure 72: White-tailed Deer - NISP

### **Moose**

There is some disagreement as to the range of moose (*Alces alces*) in southern and central Ontario. Peterson's research (1955:17) argues that data from the nineteenth century indicate that moose did not range south of the Canadian Shield, but Banfield's (1981:397) map suggests they did inhabit the north shore of Lake Ontario in the past. Peterson's suggestion seems more reasonable for the 1500s as moose prefer areas of secondary growth in the boreal forest with lakes and streams, which are not typical of the north shore of Lake Ontario at that time. The only positively identified moose element from the site, a worked moose metatarsal from 470-135 Post 30 fill (Cat. #11271) may therefore have originated further north. It displays a degree and extent of polish not seen on deer metatarsal artifacts, suggesting that it had been worked and then curated for some time. It is possible that it was not an artifact produced at Mantle, but was instead a finished artifact that was acquired from groups further north.

### **Wapiti (Elk)**

Maps produced by Peterson (1966) show wapiti in the southern portion of the shield in the nineteenth century. Wapiti remains from the fossil and archaeological record are commonly associated with wetlands and deciduous and mixed forests, and they appear to have ranged mostly in the southwestern and southeastern parts of the province.

Wapiti were identified from: Features 28, 73, 427, 475, 542, 568 (n=2), 630, 827, 975, 1032 (n=2), 1250, 1279; the trench (n=14); Midden 1 (n=18); midden-like concentration #2 (n=4); 410-140 Post 6, 395-155 Post 46, 420-185 Post 9, 350-165 Post 9, 435-180 Post 27 (n=2), 425-170 Post 22, 485-170 Post 8; and squares 400-140, 524-143, 465-155 (see Appendix M). Teeth, vertebrae, and longbones are present, but most remains are tarsals, metatarsals, and phalanges.

There are 112 remains that are either deer or wapiti based on element size, although none were so big as to exclude deer. Twenty-five fragments are either wapiti or moose based on size (Features 335, 340, 385, 390, 435, 465, 475, and 530; two adjacent squares in Midden 1 (n=5); six squares in midden-like concentration #2 (n=9), of which two are touching; Post 7 from 550-160; and 465-155) (see Appendix M).

## **8.4 Worked Bone**

Worked bone and tools (3% of the total assemblage, n=1,166) were identified to the lowest possible taxonomic level and briefly described in a separate field in the database. In some cases, a (tentative) function was assigned.

About 23% (n=262) of the alterations appear to be use wear from contact with a substance that is softer than bone. Some of this occurs on spiral fracture margins of large mammal longbone (including deer). It seems plausible that these may be expedient hide-working tools. To prove or disprove this, these specimens would have to be analyzed microscopically or chemically for use wear. It can be difficult to interpret tool manufacture, use, and discard – and the presence of any adhering biological matter – because archaeological bone tool assemblages are mainly comprised of discarded tools: items that “failed” during manufacture or that broke during use. Tools made at Mantle that were still useable were probably taken to the next village location and may have ended up being deposited in a midden there. Therefore, residue on tools at a given site may represent plants and animals eaten or used at multiple village locations depending on the durability (or continued usefulness) of the tool.

The breakdown of worked bone by class is provided in Table 66.

**Table 66: Worked Bone Distribution by Class**

	<b>N</b>	<b># Worked</b>	<b>% of Class</b>	<b>% of Worked</b>
Crustacea	2	0	0	0
Bivalvia	405	31	8	3
Gastropoda	75	14	19	1
Actinopterygii	2,422	12	0	1
Amphibia	167	0	0	0
Reptilia	174	7	4	1
Aves	817	114	14	10
Mammalia	32,798	964	3	83
Aves or Mammalia	356	22	6	2
Class Unknown	326	2	1	0
<b>Total</b>	<b>37,542</b>	<b>1,166</b>	<b>3%</b>	<b>100%</b>

As noted earlier, one painted turtle marginal carapace portion (Cat. #9148, Feature 1238) was drilled, perhaps as part of a rattle, and the vertebrae on another carapace had been ground down (Cat. #11493, Post 16, 515-190).

It can be difficult to interpret tool manufacture and use and the presence of adhering meat because archaeological assemblages are mainly comprised of discarded tools: items that “failed” during manufacture or that broke during use. Tools made at Mantle that were still useable were probably taken to next village location and may have ended up being deposited in the midden there. Therefore, residue on tools at a given site may represent plant and animal foods eaten at multiple village locations depending on the durability of the tool.

Of the 272 deer proximal phalanges from the third and fourth digits (MNE 176; MNI 22), 31 were worked. As one might expect given the fact that Draper is probably ancestral to Mantle, many of these phalanges perfectly match McCullough’s (1978) description of the Draper worked deer phalanges. Of the 31 worked phalanges at Mantle, 14 were ground posteriorly. Of these 14: seven were ground on the posterior surface (Mode 1); another four were ground on the anterior surface so that the bone was worn away completely about mid-way between the epiphysis and the distal condyles, creating a hole into the marrow cavity (Mode 2); and three were ground on both the posterior and the anterior surface (Mode 1 and 2 combined). Another three were perforated distally and ground proximally and an additional three were perforated but were so incomplete that it was not possible to tell whether they were simply perforated (with the proximal end intact) or had been similarly altered. Two of the 17 wapiti proximal phalanges had also been perforated, but these are also too incomplete to determine their function. The fact that not all proximal phalanges of digits 3 and 4 had been worked suggests there were enough available for the Mantle inhabitants’ needs. But at the same time, the fact that there are 272 (fragments of) proximal, 126 intermediate, and 67 distal phalanges of deer, when in a live animal there are equal numbers of each, seems to suggest preferential retention of the proximal phalanges. The distal phalanges are rarely broken, so they have a ratio of NISP:MNE that is much closer to 1 than that of the proximal and intermediate phalanges. In other words, the relatively lower NISP for distal phalanges is no surprise, but we’d expect the NISP for the proximal and intermediate phalanges to be more similar to each other.

There are many modified Artiodactyla metapodia 3 and 4, and especially metatarsals, present at Mantle (n=123, of a total of 670 Artiodactyla metapodia 3 and 4). Of these, 42 show the kind of use wear described above and 87 show other working (6 show both); 111 are (cf.) white-tailed deer, and 12 are (cf.) deer/wapiti, wapiti, and wapiti/moose. Humanly modified deer metapodia 3 and 4 are typical for Iroquoian sites. Both metapodia tend to fracture longitudinally, but the metatarsal has the advantage that

splinters can be forced off starting in the pronounced vascular groove. The groove acts as a natural guide for scoring the outer cortex, and stages of this process can be observed on some of the fragments. A number of these metapodial artifacts have been heat altered, possibly to make them stronger. This “heat-tempering” would have required a very specific kind of fire and temperature. This would also serve to increase the proportion of this already-sturdy (and highly recognizable) element in the collection in relation to other bones in the body.

A number of formal bone tools were also recovered and the following descriptions are in part derived from Birch and Williamson (2013). Several perforating devices, commonly called awls, were recovered. One was manufactured of deer metatarsal 3 and 4 and is ground, polished and decorated with incised chevrons of different sizes and spacing, as well as oblique, vertical, and horizontal lines along its entire length (Plate 99). Some of these designs perhaps represent lightning energy symbols or journey or snake manifestations (Williamson and Veilleux 2005).

Plate 99: Bone Awl decorated with incised chevrons.

Two complete items that are likely thin needles for manufacturing fishnets (or perhaps webbing on snowshoes) were also recovered (among a total of 21 items of netting needle-like tools and manufacturing waste). One appears to have been fashioned from a piece of dog-sized mammal longbone that has been ground flat and then tapered at both ends and perforated about halfway along its length. The other is likely made from deer longbone given the distribution of NISP. It is also ground flat and tapered at both ends and is perforated approximately one-third of the way along its length. The fact that these items are largely intact, despite their extreme thinness, is probably due to their relatively small “eye,” rendering them less susceptible to breakage at the point of perforation (Plate 100).

Plate 100: Select Bone Tools

Pendants include mammal teeth, including a dog lower canine that had been perforated transversely through the root. The perforation is intact and there is use wear or polish on the root; the enamel of the tip was worn or removed by spalling (Plate 101). A number of bear canines were also recovered, one of which had cracked at the point at which the root narrows near the tip, perhaps as a result of attempts at modification to facilitate its attachment to a cord. In all, 43 of the 60 mammal canines showed (possible) signs of working or curation.

The Mantle assemblage contained 69 beads, likely beads, and bead-making waste. Of these, three were perforated gastropod shell (either beads or pendants), 31 bird longbone shafts, and 33 mammal longbone or *Canis* sp. metapodial shafts. Many of the longbone beads still exhibit part of the groove that was used in the groove-and-snap manufacturing process. Unusually, one deer distal phalanx was also ground at both ends, resulting in something that could have functioned as a bead or pendant. Only four complete beads were recovered. One of these is a piece of bird or mammal longbone that had been ground perpendicular on both ends and highly polished on the outer cortex – perhaps intentional polish rather than that resulting from use (Plate 101). An especially interesting and rare artifact from Mantle is a composite artifact, likely a pendant, manufactured from two beads, the shorter a piece of bird longbone and the other a fragment of metapodial of a wolf or dog. The beads are of different lengths, both with ground ends and polished surfaces, the longer of which was inserted within the shorter, wider one and fastened permanently (Plate 101). The major portion of the inserted bead, which extends below the short one, is marked with two alternating series of short notches on the two margins of the piece, ten visible on one side and eight on the other. It is not known if other notches are present within the seated portion of the bead. Small incised lines or scores are evident between the notches. While the composite construction of the artifact is rare in Iroquoia, the use of transverse incisions or short notches to decorate beads is not, appearing on over 65% of decorated specimens (Williamson and Veilleux 2005:21), often evenly spaced.

Plate 101: Select Bone Beads and Pendant

Another notched bead is manufactured from a mammal longbone, perhaps a dog radius that has been ground considerably and then notched where the bone flattens in circumference. There are four notches on one lateral side of the bead and three on the other (Plate 101). The notches on this bead are wide and deep and resemble those on the necks and collar bases of certain ceramic vessels on the site.

There were also a number of possible worked antler pieces, including some major sections of a rack. Jin and Shipman (2010) have recently illustrated that damage to antler while the deer is alive can look remarkably like intentional working or use by humans, and it is likely that at least some, if not a large proportion, of the antler marked as “worked(?)” in the database is, in fact, naturally broken/damaged.

Only one formal artifact manufactured of antler (probably moose based on shape and size) was recovered; it consisted of a unique three-toothed, comb-shaped pendant found in four pieces from adjacent screened one-meter units in the northwest quadrant of the site (Plate 102). While the surface of the body of the piece is evenly polished, there is enhanced wear and polish around the hole from which it was suspended. There are evenly spaced lateral incisions across the body of the artifact from the base of the teeth to its head on one side and from the base of the teeth to the bottom of the hole on the other, the remainder perhaps erased through wear. Carved antler combs, whether intended for use as a comb or pendant, are extremely rare on ancestral and historic Wendat sites; present on Neutral sites, in particular in the historic period; but common from the sixteenth century to the late seventeenth century on Iroquois, especially Seneca, sites (Williamson and Veilleux 2005:8–16).

Plate 102: Select Bone Beads and Pendant

## **8.5 Discussion**

The faunal assemblage at the Mantle site contains a wide range of species, but this is in part a function of the extremely large sample size, which would capture more rare taxa than a smaller sample. The terrestrial habitats exploited by the site occupants appear to be mostly fields and forest edge, deciduous growth, some stream areas, but also include some deeper forest and cedar swamp. The number of fish bones is low compared to many other sites (except Draper); however, there are so many taphonomic factors working against survival and recovery of fish bone that the percentages do not necessarily imply that fish were not important. Within the fish remains, there seems to be an emphasis on the mass capture of fall-spawning fish that are amenable to storage, namely, lake trout, whitefish, Atlantic salmon, and eel. Another focus is on suckers, which are most readily caught during their spawning run in spring, but which can be caught at other times.

If proportions of bone fragments from different taxa are interpreted as representing those taxa present at the site, it would seem the diet at Mantle consisted overwhelmingly of larger mammals, specifically dog and deer. The high ungulate productivity of the area around the site is likely reflected in the relatively high percentage of deer. Deer body portion representation indicates that at least some of those deer were brought back to the village with the head attached. In the case of deer, the head is not necessarily a low-utility element, since the brain can be used in hide tanning (see, for example, Boren et al., 2004). The ubiquity of dog remains suggests that dog may have been part of the everyday diet as well as being sacrificed at times of feasting, but this is complicated by the fact that dogs were also kept as pets (Tooker 1969).

In clearing land for fields, the site occupants would have created forest edge habitats attractive to a wide range of species, including deer. Some of these animals were a threat to the agricultural crops and were likely killed in part for that reason. The collection contained evidence of the presence of many smaller mammals, some of which may have been part of a garden-hunting complex and/or desired for their fur.

The body part distributions of some of the rarer, small, fur-bearing species suggest that many of these were simply parts of pelts with attached bones. These pelts may have been acquired by trade. The worked moose metatarsal was almost certainly acquired this way.

## 9.0 HISTORIC ARTIFACT ANALYSIS

Anatolijs Venovcevs

### 9.1 Historic Context

In order to place the Euro-Canadian archaeological remains from the Mantle site within the context of historical land use, research was conducted at the Ontario Archives. The site is located on part of Lot 33, Concession 9 in the Geographic Township of Markham. According to the Abstract Index to Deed Titles, the Crown Patent for Lot 33, Concession 9, comprising all 200 acres was issued to Graney Curtis in 1802. Then, in 1808, William Curtis sold the lot to Simon Morton who in turn sold it to Jonas Byers that same year. In 1836, Jonas Byers sold the entire 200 acre lot to Samuel Byers (sometimes spelled “Boyers” or “Boyer” in the records). Samuel Byers held onto all of the 200 acres until he sold a portion of the west half of the property to the Toronto-Nippissing Railway Company in 1870 and the rest of the property to Jonas Byers in 1878 [AO, *Abstract Index to Deed Titles*, Markham Township, reel GSU 179631].

In order to confirm whether or not the Byers family occupied Lot 33, commercial directories and assessment rolls were examined for residents of Markham Township listed with that address. Samuel “Boyer” was listed with the address of Lot 33, Concession 9 in Walton’s 1837 *Home District Directory* (Walton 1837:101), which indicates that Samuel Byers did inhabit the property after buying it from Jonas Byers. Samuel “Boyer” was again listed in the 1846 *Brown’s Home District Directory* (Brown 1846:46).

By 1851, the land was occupied by a tenant, James Bugg. James Bugg was enumerated in the Markham Township census as a 33 year-old English farmer residing with his 29 year-old wife, Rebecca, their two Canadian-born children aged seven and four, and two non-related individuals, Elizabeth Mallow (aged 20) and Robert Kromburg (aged 16). The family lived in a two-storey brick house and occupied 200 acres of which 20 acres were cultivated, 46 acres were under crops, 33 acres were pasture, one acre was garden, and 100 acres were wooded. Assuming that a family could clear two to four acres of land a year, it can be extrapolated that the clearing began in the 1820s. The family cultivated wheat, barley, peas, and oats and had oxen, milk cows, horses, sheep, and pigs. A saw mill was enumerated on the property. It processed 40,000 square feet of timber per year [AO, *Markham Township Census*, reel C-11759].

James Bugg continued to occupy the property according to the 1861 census. He was enumerated as a 42 year-old English born sawyer and yeoman who occupied the property with his 36 year-old wife, their three children aged 16, 13, and four, and 28 year-old Mark Kirk. They continued to reside in a two-storey brick house. Out of their 200 acres, 20 were cultivated, 85 were under crops, 10 were pasture, five were gardens, and 80 acres were woodland. They cultivated wheat, peas, buckwheat, oats, potatoes, turnips, and mangle wurzel. The family owned bulls, milk cows, horses, sheep, and pigs and their entire farm was valued at 10,000 dollars. The saw mill continued to be in operation. It had 1,000 dollars worth of capital and utilized 500 logs of pine and hardwood valued at 375 dollars to produce 250,000 square feet of sawn wood valued at 1,000 dollars. The mill utilized water power and employed one person that was paid 25 dollars a month [AO, *Markham Township Census*, reels C-1088 and C-1091]. The 1860 *Tremaine Map of County of York* confirms that James Bugg occupied the property while Samuel “Boyer” was the owner. The map also depicts the saw mill and a house in the vicinity of the Mantle site.

The 1871 census returns did not enumerate any land being farmed on the property for that year and neither Samuel Byers nor James Bugg were listed in the enumeration district that contained Lot 33, Concession 9. According to Schedule 6, only one saw mill operated in the enumeration district but its address was not given. It was owned by Edward Wheeler and had 1,000 dollars worth of fixed capital and 3,000 dollars worth of floating capital. It was steam and water powered with a force of 20 horse power

and worked for 12 months out of the year. Three men and one boy were employed with combined wages of 800 dollars a year. The mill processed both lumber and wheat and produced 650,000 square feet pine, elm, and hardwood lumber valued at 10,000 dollars [AO, *Markham Township Census*, reel C-9969]. Given that the 1878 *Illustrated Historical Atlas of the County of York* does depict a mill on Lot 33, Concession 9, it is possible that Edward Wheeler's mill is the same one that James Bugg operated in 1851 and 1861. Augmentation of water mills through steam power was a popular upgrade in the second half of the nineteenth century in Ontario to overcome the lack of water flow during the winter months and at times of severe drought. The 1878 map shows the lot as the estate of "Sam Byer" and depicts a house with a laneway and a grist and saw mill within proximity of the Mantle site.

The 1901 census once again did not enumerate any land being farmed on Lot 33, Concession 9 and it did not contain a reference to a mill [AO, *Markham Township, Assessment Rolls*, reel T-6506]. The 1917 topographic map of Markham Township did not depict a building in the mill's former location indicating that it probably ceased operation prior to 1911, as was suggested by Stanley Mantle, a previous land owner. It was also recollected that the farmhouse that stood on the property prior to its demolition in 2002 was constructed around 1880-1890 (Stanley Mantle, personal communication, July 2011). Two late nineteenth/early twentieth-century barns also stood on the property approximately 75 metres south of the house. These were torn down in 2002 as well (Stanley Mantle, personal communication, July 2011).

To summarize, bringing Lot 33 into agricultural production began with Jonas Byers sometime after he purchased the property in 1808. While Samuel Byers occupied the entire 200 acre lot in 1837 and 1846, by 1851 he chose to live elsewhere. Next, James Bugg and his family established themselves on the property and lived in a two-storey brick house and operated a water-powered saw mill until sometime before 1871. The mill continued to operate until 1911 with the introduction of a steam back-up power source and the diversification of the operation by adding a grist milling component. Between 1871 and 1901 there is no evidence of the land being used for agricultural production but a new farm building could have been constructed at this time. The farmhouse and its associated barns were torn down in 2002.

## 9.2 Euro-Canadian Settlement Patterns

The Euro-Canadian settlement patterns can be divided into two components. The first component consists of the foundations of the late nineteenth-century farmhouse and the former late nineteenth/early twentieth-century barns that stood on the property until 2002 along with midden-like concentration #2, midden-like concentration #3 and 25 Euro-Canadian features. Most of the Euro-Canadian features were confined in the area of the southern-most barn and five of them represented sub-adult animal burials. The animal burials consisted of two baby calves, one juvenile calf, a sub-adult left hind leg and pelvis of an ill horse, and a feature that contained elements from two sub-adult cows and one horse tibia. The proximity of the burials to the barn suggests that these animals died from disease or were still born and thus were buried around the barn. Miscellaneous Euro-Canadian posts scattered around the barns and the former house foundation would probably relate to the late nineteenth and early twentieth-century occupation of the property. Closer to the farmhouse, midden-like concentration #2, midden-like concentration #3 consisted predominantly of displaced soil caused by the demolition of the Mantle farmhouse.

The second component consisted of the partially-excavated Midden 1 which was located approximately 85 metres away from the features by the late-nineteenth/early twentieth-century barns. Most of the Euro-Canadian artifacts came out of this context. This area was located halfway between the former Mantle farmhouse, the former mill dam, and the approximate location of the former saw mill as derived from historical photographic evidence (Plates 103-104), historic atlases, and background information supplied by Stanley Mantle (Figure 73). Given its location, the Euro-Canadian material from Midden 1 may relate either to the farmhouse, the mill, or another separate occupation. The interpretation of this context is further complicated by a stone foundation wall that was identified on the northern side of the block

excavated area. This foundation wall represents the location of an indeterminate building that is related to the mill as can be seen in a historic photograph of the milling operation (Plate 105).

Plate 103: Historic photo of the mill dam on Lot 33. The building whose foundation was identified in Midden 1 is seen on the far right just below the 1880-1890 farmhouse in the top right. Date of the photograph is unknown.

Plate 104: Historic photo of the mill on Lot 33. Note the mill dam is on the left and the 1880-1890 farmhouse in the top centre of the photo. Date of the photograph is unknown.

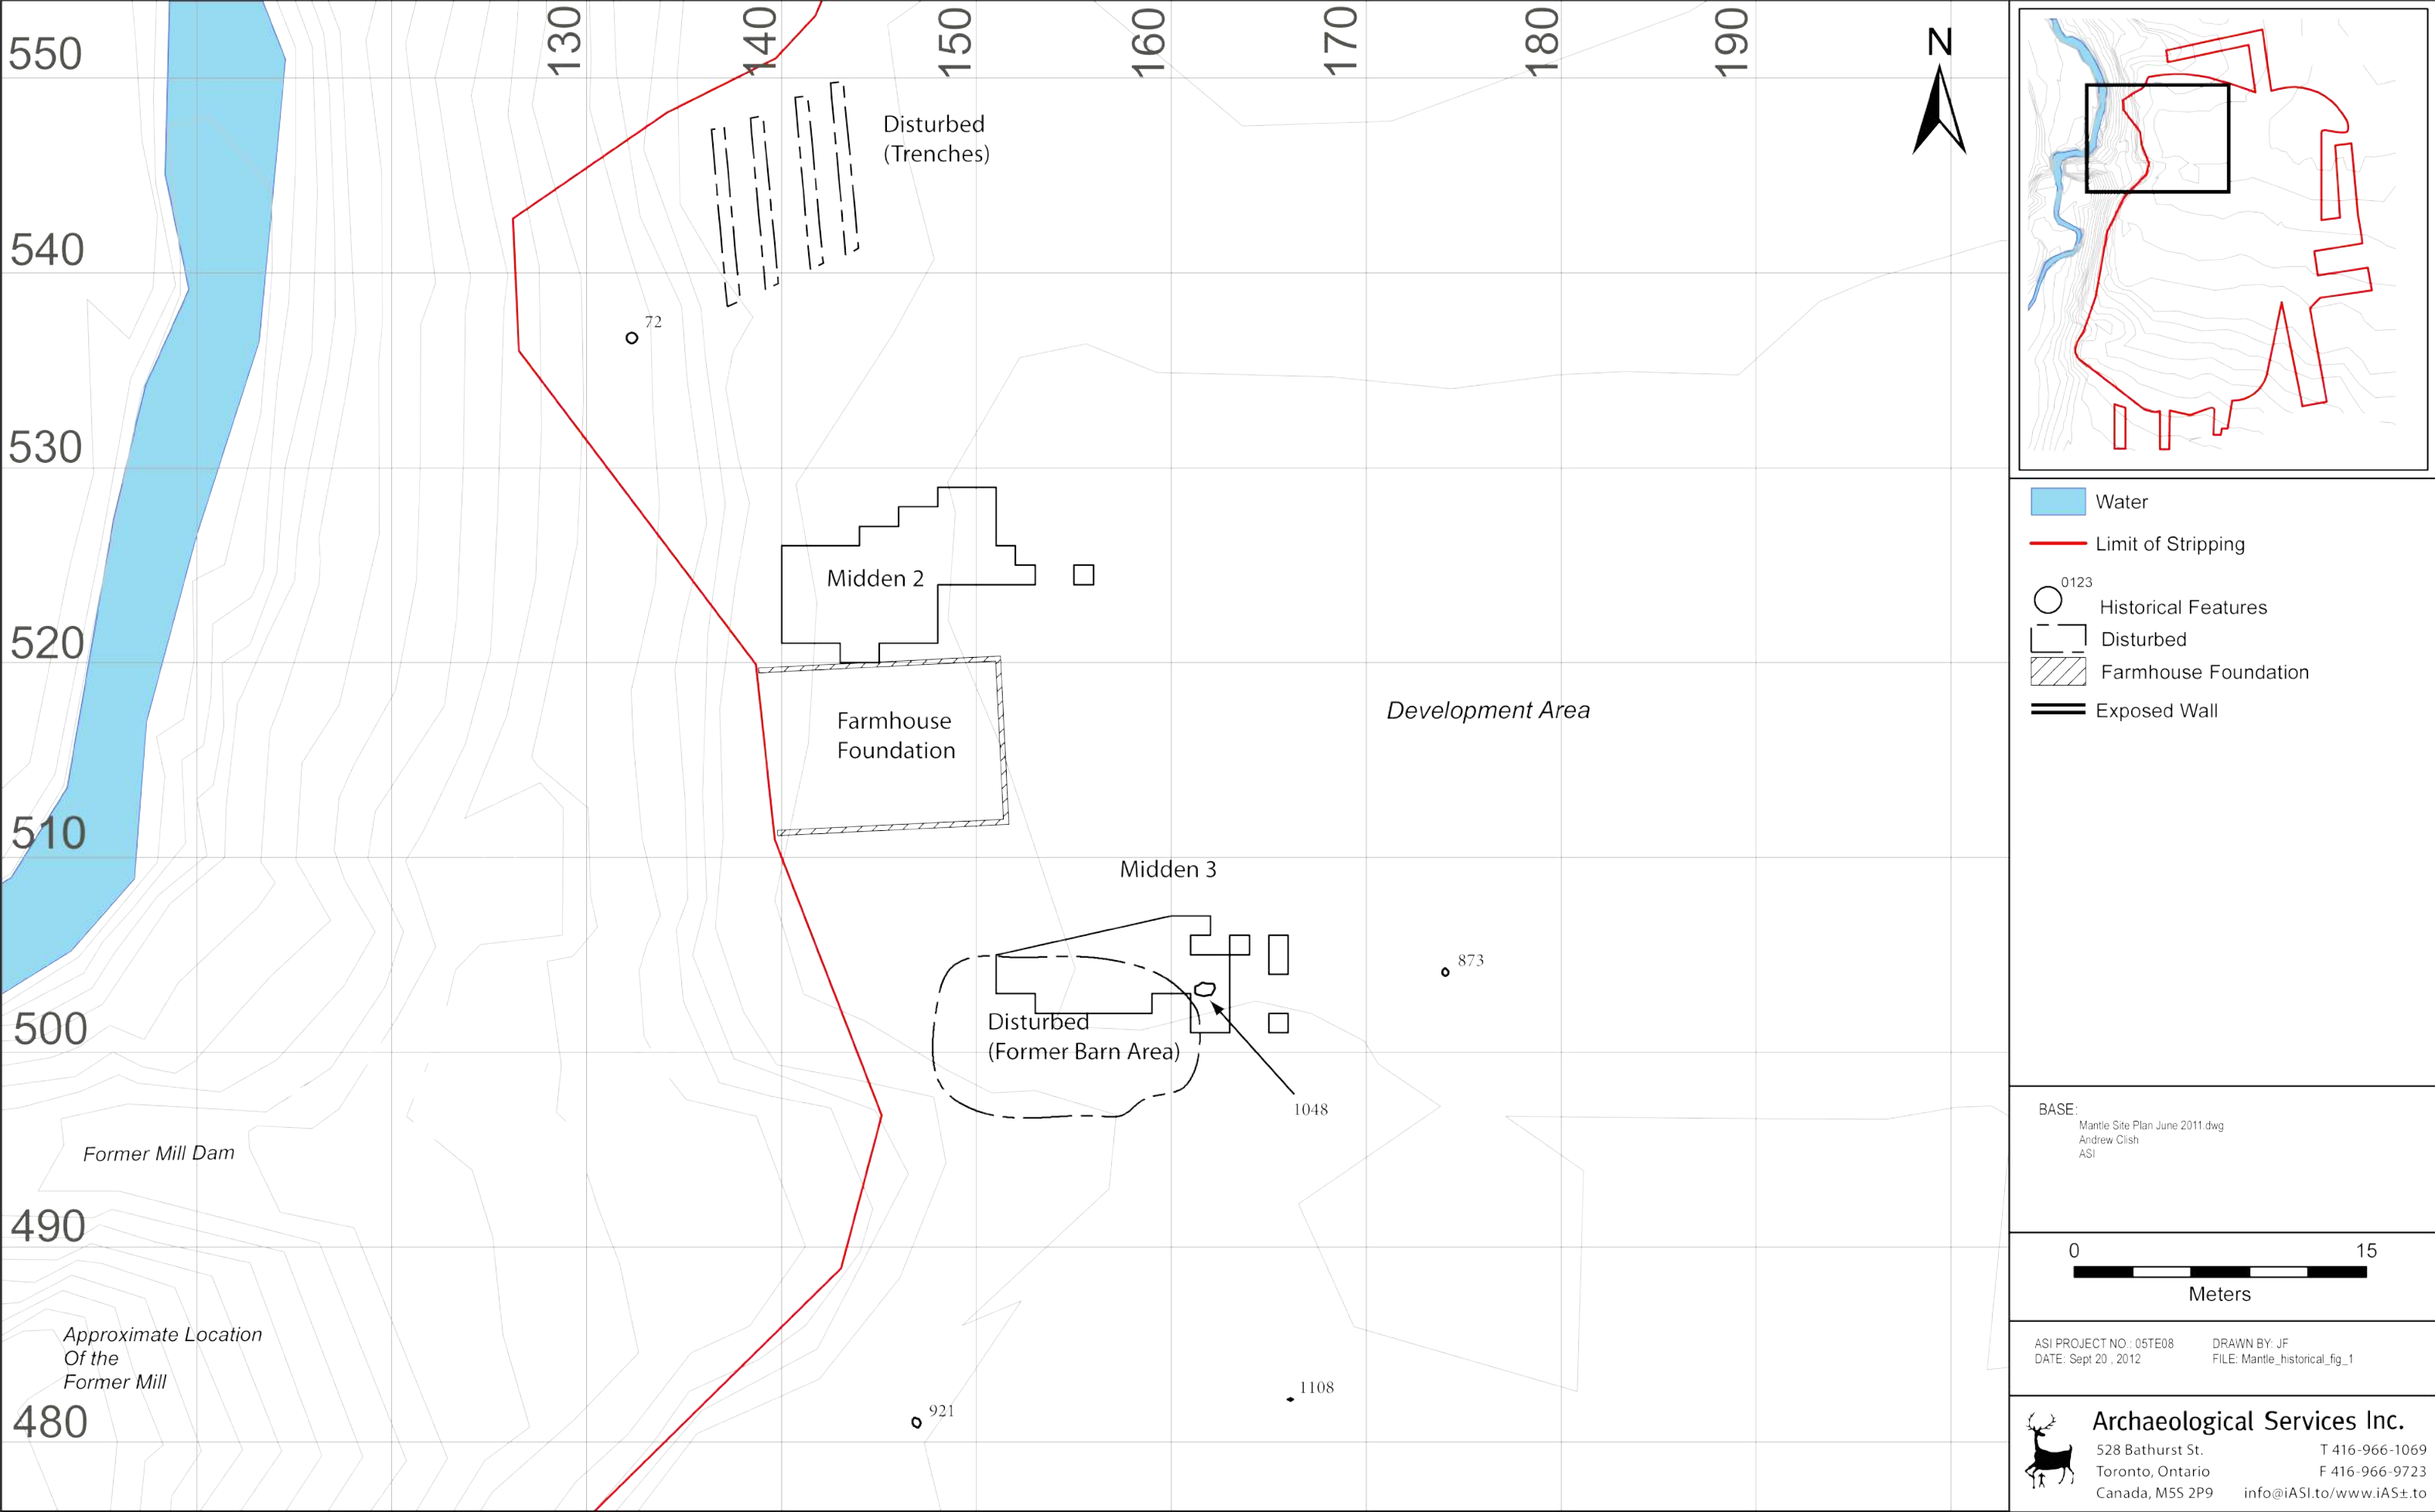

Figure 73: Historic Features and Artifact Distribution around the Middens

encountered in Midden 1

### 9.3 Euro-Canadian Artifact Distribution

A total of 6,612 Euro-Canadian artifacts at the Mantle site (AlGt-334) was recovered from all three middens and nine out of the 25 Euro-Canadian features. Their distribution across the site is summarized in Table 67 below.

**Table 67: Distribution of Euro-Canadian Artifacts at the Mantle Site (AlGt-334)**

Provenience	Artifact Yield	Percent of Total
Surface	23	0.3%
Midden 1	6,480	98.0%
Midden 2	20	0.3%
Midden 3	12	0.2%
Post mould 4 in unit 380N-135E	2	<0.1%
Post mould 9 in unit 415N-135E	1	<0.1%
Post mould 27 in unit 435N-180E	5	0.1%
Feature 47	1	<0.1%
Feature 48	3	<0.1%
Feature 49	35	0.5%

Almost all of the Euro-Canadian material was recovered from Midden 1 and, as previously mentioned, this material relates to the farmhouse and the mill that stood on Lot 33. Midden 2 and Midden 3 contained only a few Euro-Canadian artifacts and represents displaced material from the demolition of the nineteenth-century farmhouse (Figure 73). Other artifacts were recovered from animal burials and miscellaneous Euro-Canadian features that were concentrated in the southwest corner of the site (Figure 74). Most of these features were adjacent to the former late-nineteenth/early twentieth-century barn. Within Midden 1, Euro-Canadian artifact yields ranged from eight in unit 501N-124E and 527 in unit 500N-123E.

Since previous studies have demonstrated the utility of analyzing the distribution of artifacts in block excavated units (King 1988; Poulton and Dodd 2007), it is important to note the distribution of some key artifact types within Midden 1. As can be seen in Figure 75, Euro-Canadian artifacts were fairly evenly distributed south of the historic wall foundation in Midden 1. The early nineteenth-century ceramics, represented by creamware, pearlware, Jackfield, and mid-nineteenth-century ceramics, represented by refined white earthenware, follow this pattern and display no significant concentration. Architectural items, on the other hand, cluster differently. Window glass is concentrated in the northwest corner of the midden adjacent to the historic wall foundation while the nails are distributed fairly evenly throughout the midden including the southeast corner, away from the concentration of window glass.

As seen in Plate 103, the small ancillary mill structure identified during the Stage 4 excavation contained windows whose presence and possible location can be derived from the distribution of window glass in the northwest corner of Midden 1. The fairly even distribution of nails within Midden 1, especially in the southeast corner where the window glass is not as plentiful, suggests the presence of other windowless ancillary mill structures south of the excavated area. On the other hand, the even distribution of early and mid-nineteenth-century ceramics within the excavated area suggests that the kitchen and food refuse disposal did not change over the course of Jonas and Samuel Byers' and James Bugg's occupation of the property.

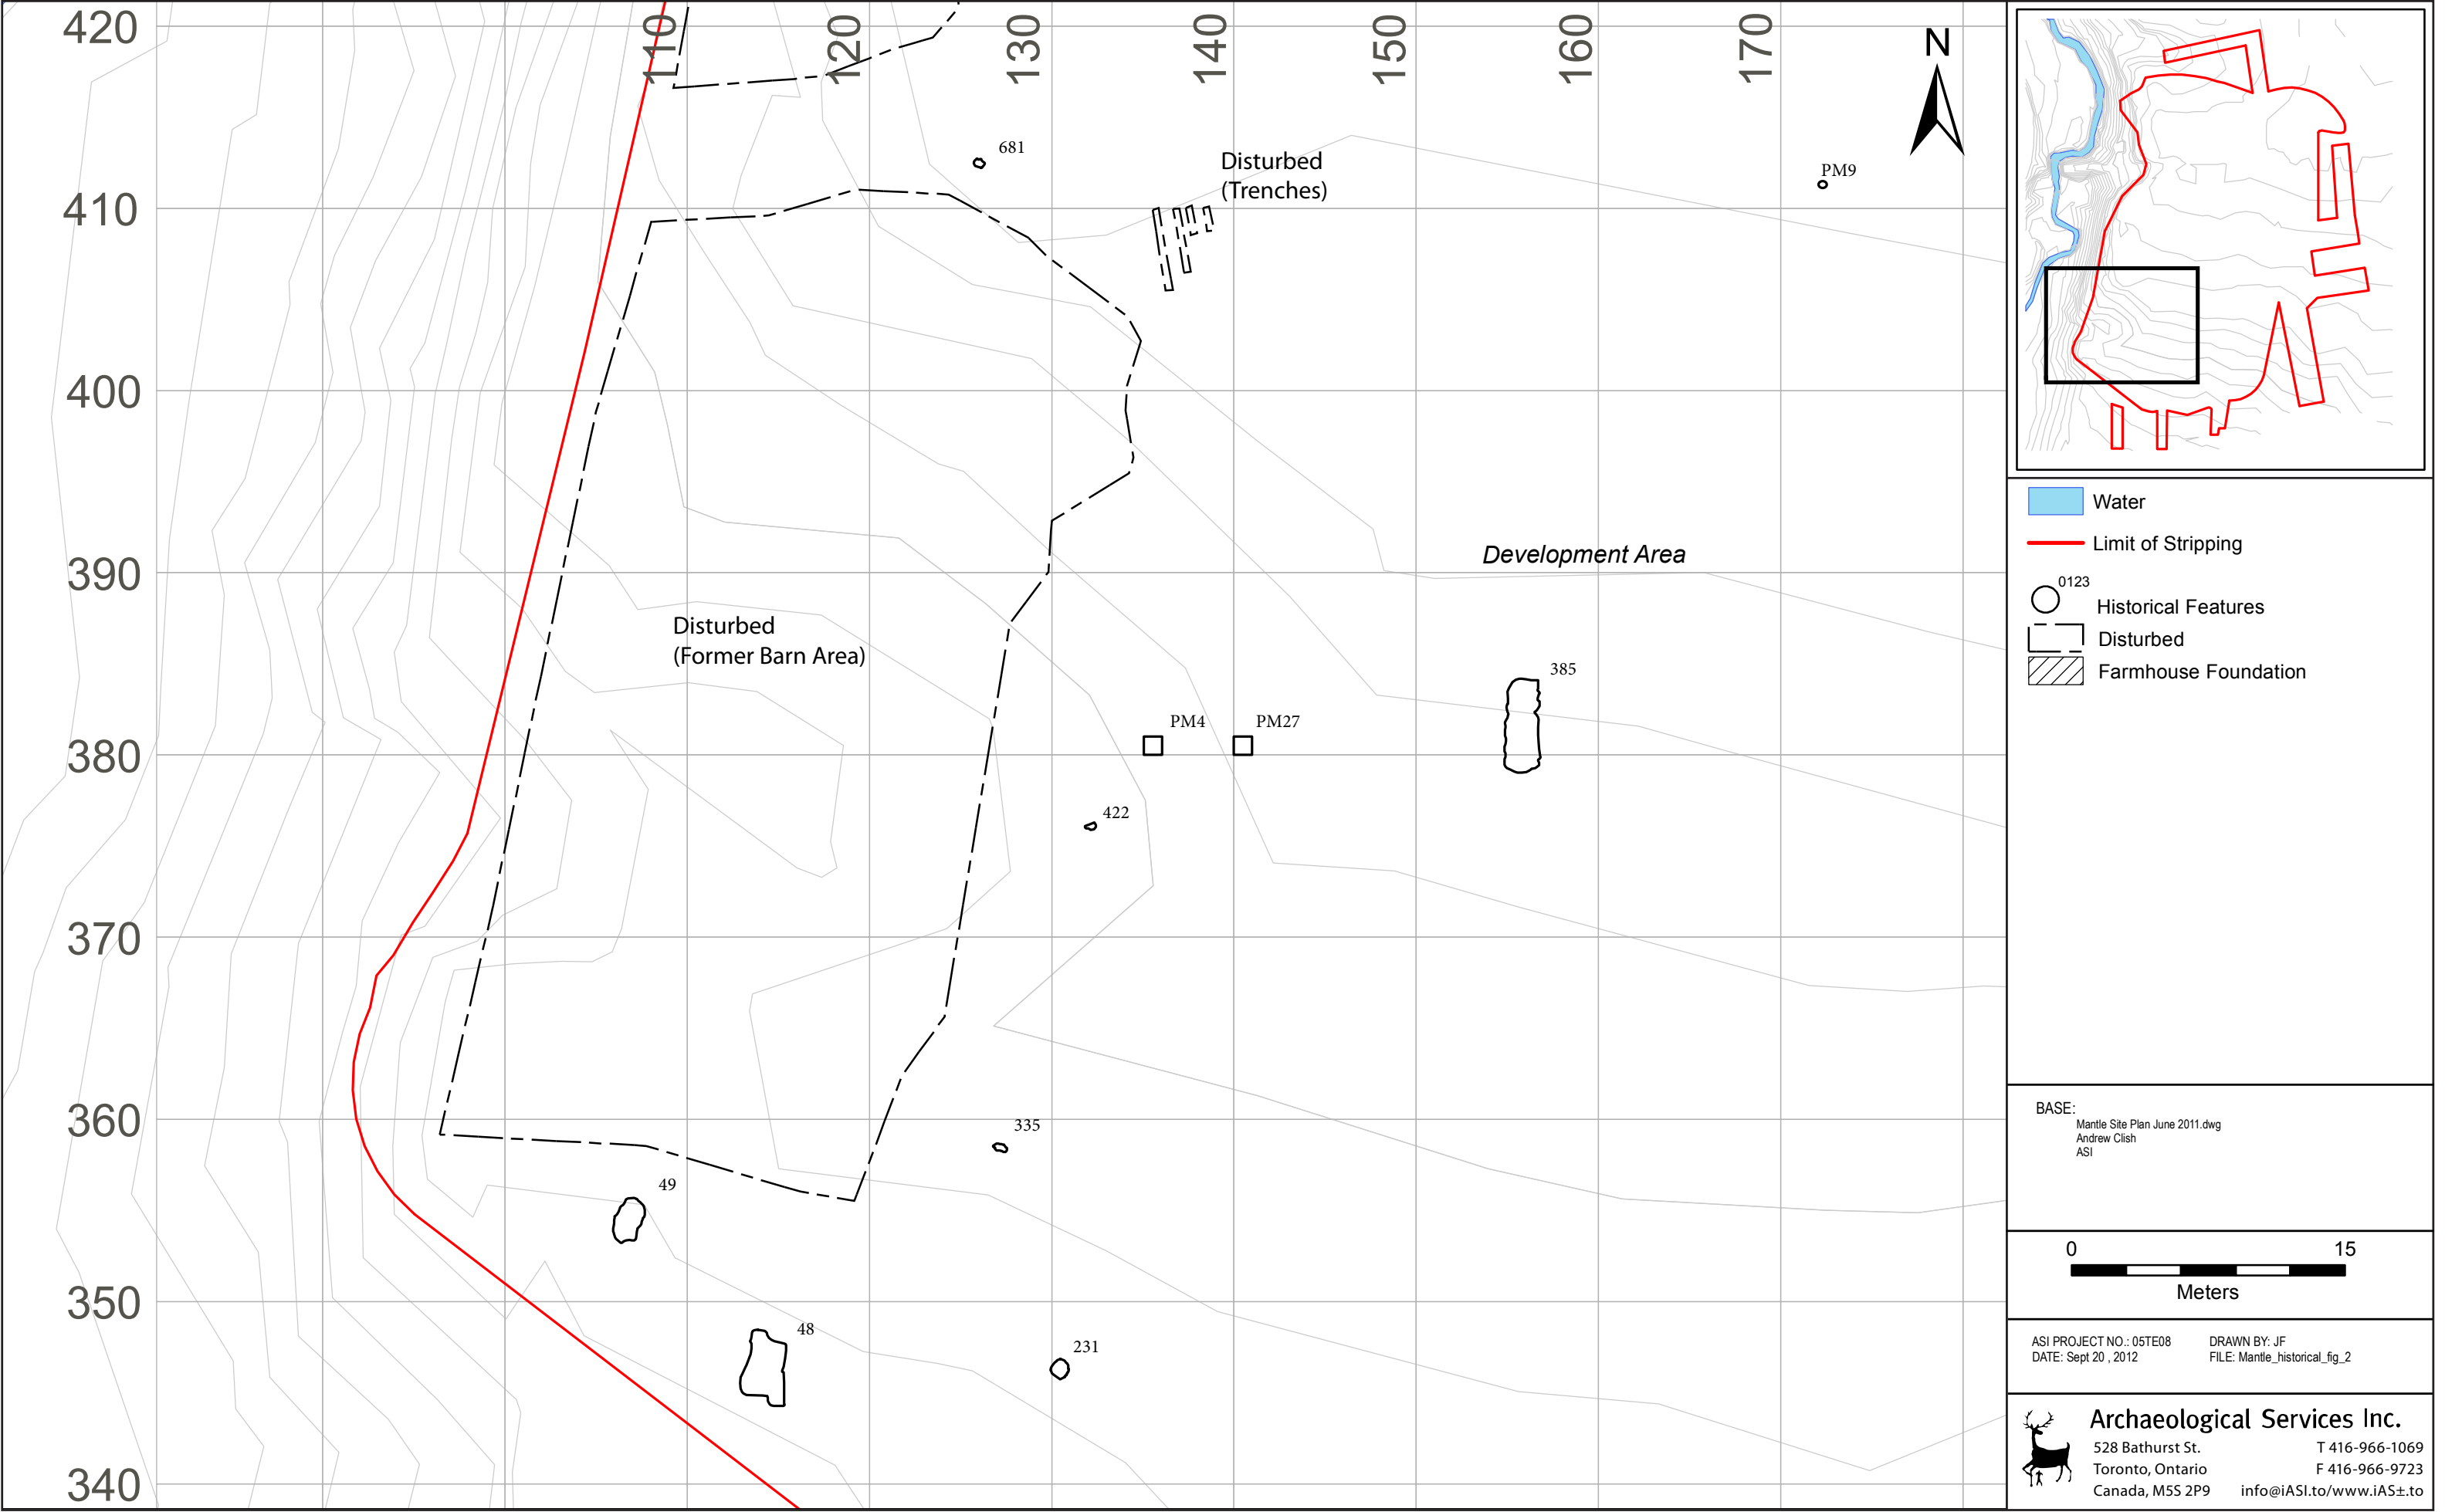

Figure 74: Historic Feature and Artifact Distribution around the Former Barns

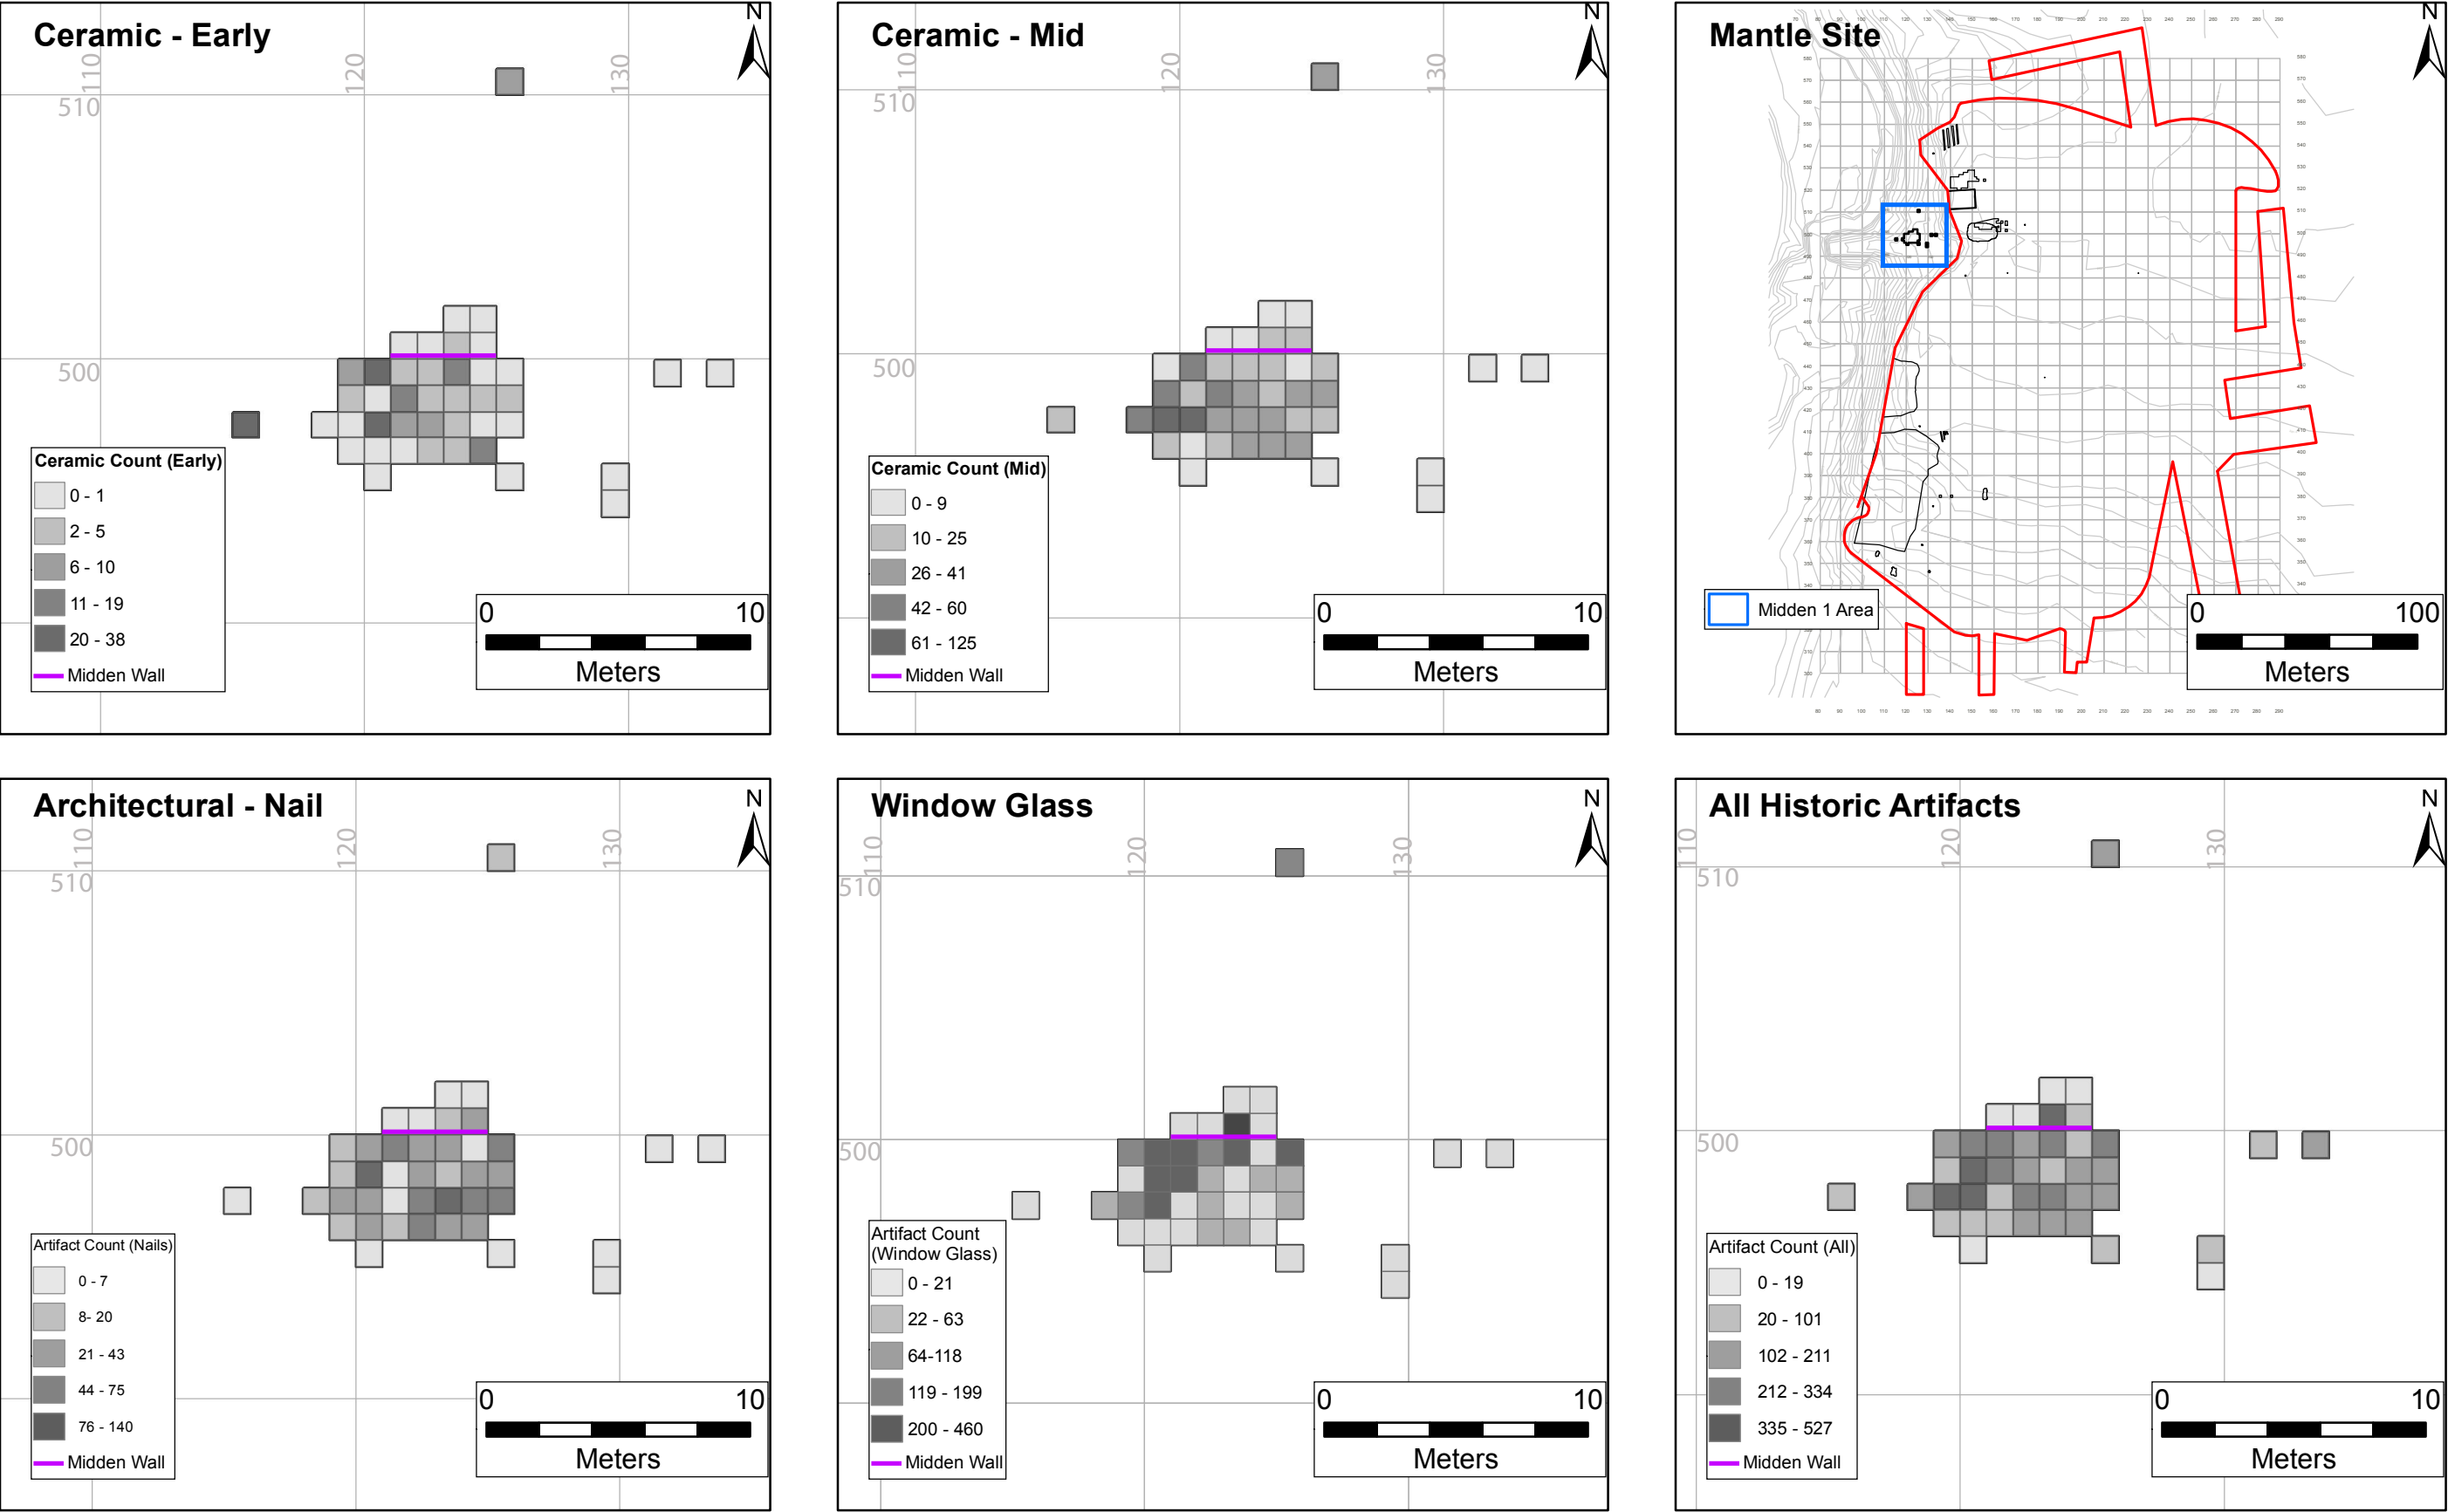

Figure 75: The Dtribtion of Euro-Canadian Atrifacts in Midden 1

## **9.4 Euro-Canadian Artifact Inventory**

In total, 6,612 Euro-Canadian artifacts (Appendix O) were recovered during the Stage 4 mitigative excavation of the site. These are summarized by function and provenience in Table 68 below. A modified “Classification System for Historical Collections” (Canadian Parks Service 1992) was used to organize the data.

### **9.4.1 Architectural Class**

Artifacts from the architecture class comprise 60.0 percent (n=3,968) of the total Euro-Canadian artifact assemblage found at the site (AlGt-334). In this assemblage there are 36 hand-wrought nails that pre-date the 1830s, 1,187 machine-cut nails that date to between 1830 and 1900, 34 wire nails that post-date 1900, and 48 indeterminate nails (Table 68 and Appendix O; Kenyon 1982). Other architectural material consists of one bracket, six brick fragments, one piece of cement mortar, three door hinges and three door strike plates, 16 pieces of drainage tile, seven pieces of lime mortar, two twentieth-century roofing nails, and 2,624 pieces of window glass. Like most Euro-Canadian material, most of the architectural items were recovered from Midden 1 (Table 68 and Appendix O). The large amount of machine-cut nails recovered from Midden 1 suggests that a nineteenth century structure stood in the area. The small amount of hand-wrought nails points to a pre-1830s component of the structure while the wire nails indicate that structures were refurbished during the twentieth century. The presence of lime mortar is also significant as lime mortar was employed exclusively in the nineteenth century. After the year 1900, concrete mortar became the popular material to bind brick and stone together (McIlwraith 1999:94-96).

### **9.4.2 Furnishings Class**

Fifty-five furnishings class artifacts were recovered from the site. They consist of three figurine fragments, 10 terracotta flower pot sherds, three pieces of furniture, one door key, 37 pieces of lamp chimney glass, and one mirror (Table 68 and Appendix O). The furniture pieces consist of one drawer plate, one drawer handle, and one cupboard door handle (Appendix O).

Lamp chimney fragments became common on Euro-Canadian sites in the later years of the nineteenth century as the dropping price of kerosene made glass lamps more affordable (Woodhead et al. 1984). All but one lamp chimney fragment was recovered from Midden 1. The lamp chimney glass from the Mantle site consists of 24 body fragments, six decorative filial fragments, and seven rim fragments. Most of the body fragments appear to be from an oil lamp while six rim fragments are decorated with mitres and panels in a rectangular pattern and appear have been part of a twentieth-century table lamp. One rim fragment and decorative filial fragments are made from twentieth-century milk glass and are probably from a twentieth-century table lamp as well (Appendix O).

### **9.4.3 Kitchen/Food-related Class**

The Stage 4 archaeological assessment of the site produced 1,986 kitchen and food-related artifacts comprising 30.0 percent of the Euro-Canadian artifact assemblage (Table 68 and Appendix O). These artifacts relate to the storage, preparation, distribution, and consumption of food and beverages.

#### *Ceramics*

Ceramics are a useful tool for dating archaeological sites because of the historical progression of types in industrial-era ceramic production. Much of the innovation that took place in the late eighteenth century English ceramic industry resulted from the competition with the imported porcelain market from continental Europe and China (Kaellgren 2009:13). Thus in the mid-eighteenth century the English potters began experimenting with a particular new type of ceramic: refined cream-coloured earthenware. It was produced as early as 1740 by Enoch Booth but was perfected by Josiah Wedgwood in 1762 and quickly became attractive and popular as a status ware (Copeland 1995:4-6). As the name might suggest, creamware is creamy in colour due to the lead glaze applied to the vessels. However, the creamware glaze lightened in colour progressively during the early nineteenth century (Majewski and O'Brien 1987:117). It continued to be produced and imported into Ontario until the 1830s though its popularity declined significantly in favour of pearlware (Kenyon 1995).

Pearlware was invented as an alternative to creamware in the mid-1770s to keep the middle class refined earthenwares competitive with the porcelain market. Potters tried to imitate Chinese porcelain with this new ware type by adding a small amount of cobalt oxide to the glaze and creating a slightly bluish tint (Miller and Hunter 2001). Decorated with a variety of mostly blue motifs, it outnumbered creamware sales by the early 1800s. Pearlware vessels continued to be sold in Ontario until the mid-1830s, when they were replaced with refined white earthenware (Kenyon 1995). Other ceramics that were produced at this time included Jackfield, a refined red earthenware vessel form with a glossy black glaze that was popular in tea services (Jouppien 1980:27).

In competition with the local English bone china market, refined white earthenware was slowly developed from pearlware by reducing the amount of cobalt in the glaze and adding it to the body, thus effectively making the ceramic white in colour (Majewski and O'Brien 1987:119). It grew in popularity due to the fact that many different underglaze colours looked better on a white-bodied ceramic than they did on the light-blue pearlware (Collard 1984:114). Thus, almost always decorated, refined white earthenware quickly became the most popular ceramic of the mid-nineteenth century (Majewski and O'Brien 1987:120).

Later, ironstone, or white granite as it was also termed, started being produced in England in the 1840s as a heavier, cheaper alternative to the influx of hard paste porcelains from France into the markets of Canada and the United States (Majewski and O'Brien 1987:120). Due to its very hard durable body it became ubiquitous in frontier households. It started appearing in Ontario merchants' records in 1847 and grew in popularity steadily during the late nineteenth century, peaking in the 1880s.

To replace ironstone, semi-porcelain, a lighter, thinner variety of ceramic exhibiting more delicate floral or abstract motifs, grew in popularity. It was introduced in the 1880s and started getting popular through the last decade of the nineteenth century (Kenyon 1995:13). However, the price of early semi-porcelain made it prohibitively expensive, but, as the price continued to drop at the turn of the century, it became a common household item by the 1910s (Kenyon 1995:13; Majewski and O'Brien 1987:124).

Another late nineteenth-century ceramic type was yellow ware. Yellow ware was primarily produced by American manufacturers in the northern states due to the predominance of buff coloured clay and the

influx of English potters into North America (Gallo 1985:17). Yellow ware started appearing in merchants records in Ontario around the same time as ironstone and was used primarily as kitchenware (Kenyon 1995). Some variants of it are still used today though its production tapered off in the United States by the 1930s (Leibowitz 1985:9).

Less chronologically diagnostic ceramics consist of coarse red and buff earthenwares. Red and buff earthenwares are heavy, thickly potted ceramic types that receive their names from the colour of the clay after firing – red and buff respectively. As they are porous, they had to be glazed to make them food safe. Usually coarse earthenware pots were produced from local clay at local potteries in contrast to the refined ceramic types that were imported into Canada. The local Ontario manufacturing of coarse earthenwares began as early as the late 1820s when the German-speaking potters immigrated into the areas of Waterloo County and the Niagara Peninsula (Newlands 1979:22).

Porcelains are also not always chronologically diagnostic. Even though porcelain was manufactured as early as the seventh century AD in China, it was not exported to Europe in significant quantities until after the fifteenth century and the English colonies until the eighteenth (Majewski and O'Brien 1987:125-126). Europeans were only able to recreate china in the eighteenth century, with the first commercially viable version being bone china first marketed in England by Josiah Spode during the 1790s (Majewski and O'Brien 1987:126).

The Kitchen/Food-related ceramic assemblage from the site contains 1,932 sherds. The chronologically relevant ceramics consist of 26 creamware sherds (1.4 percent of the ceramic total), 18 Jackfield sherds (0.9 percent), 177 pearlware sherds (9.2 percent), 1,137 refined white earthenware sherds (58.8 percent), 121 yellow ware sherds (6.2 percent), 118 ironstone sherds (6.1 percent), and 11 semi-porcelain sherds (0.6 percent). Less chronologically diagnostic ceramics consist of 17 buff earthenware sherds (0.9 percent), 171 coarse red earthenware sherds (8.9 percent), one refined red earthenware sherd, and six English bone china sherds (0.3 percent). There are 129 sherds (6.7 percent) that could not be identified as to the ware type because they are too exfoliated or thermally altered (Appendix O).

Decorative styles on refined ceramics are a very good way to identify the age of a given assemblage. Given that decorative styles change quickly over time they offer a finer focus when assessing occupation dates of an archaeological site. A summary of these styles, as well as the date range for their availability, is presented in Table 69. Only ceramics recovered from Midden 1 were analyzed in this manner given that most of the Euro-Canadian ceramics at Mantle were recovered from this area and because this area represents a component that was separate from the features around the late nineteenth/early twentieth-century barn and farmhouse complex. Based on this table and the percentage of wares discussed above, the assemblage dates from the early nineteenth to the early twentieth century. The most intense use of the midden seems to have occurred between *circa* 1830 and 1870.

**Table 69: Refined Ceramic Decorative Styles in Midden 1 and Approximate Date Ranges in Ontario**

Style	Date Range	No. sherds	% of decorated ceramics
Hand-painted, early palette	1796-1835	8	1.0%
Hand-painted, monochrome blue	1796-1835	1	0.1%

Rockingham	1855-1890	6	0.8%
Wheat pattern	1860-1900	6	0.8%
Decalcomania	1880-present	5	0.6%
Total		796	100%

Turning to a discussion of vessel uses, 182 sherds (9.4 percent) are kitchenware, 1,213 sherds (62.8 percent) are tableware, and 537 sherds (27.8 percent) are teaware (Appendix O). The ceramics have also been sorted into a minimum number of vessels based on diagnostic rims, ware type, and distinctive decorative attributes (Tables 70-72). Coarse vessels were identified based on unique rim styles and/or overall shape. In total, 46 unique vessels were identified. These consist of four teacups, 11 saucers, one child's plate, three muffin plates, three twiffler plates, seven supper plates, six table plates, seven bowls, one jug, one milk crock, and two pots.

**Table 70: Unique Euro-Canadian Teaware Vessels on the Mantle Site (AlGt-334)**

Vessel	Cat. #	Provenience	Ware	Description

### *Non-Ceramic Kitchen/Food Related Artifacts*

There are 54 non-ceramic kitchen and food related artifacts in the Euro-Canadian component at the site. These consist of two glass liners, 38 olive green liquor container glass fragments, six utensils, and eight

table glass fragments (Table 68; Appendix O). The utensils consist of a bone handle, a plastic handle, a tablespoon bowl fragment, a broken handle and bowl of an electroplated Windsor teaspoon, and a complete electroplated Windsor teaspoon. All of these artifacts except for one of the liners and the plastic cutlery handle were recovered from Midden 1 (Appendix O).

Electroplated utensils are significant chronological markers as the technique was invented slightly before 1840 in England (Kenyon 1983). Glass liners are also chronologically significant; they were a popular type of closure on fruit canning jars in the second half of the nineteenth century (Jones and Sullivan 1989:160).

#### **9.4.4 Organic Class**

There are 60 Euro-Canadian organic objects at the site. They consist of 33 botanical remains, seven pieces of coal, six mammal bones, 12 shell fragments, and two unidentifiable faunal objects. Together, they represent 0.9 percent of the artifact assemblage (Table 68 and Appendix O).

This material includes five features by the southwestern barn that contain the buried remains of several animals. One burial, designated “post mould 4” in unit 380N-135E, contains the skeletal remains of a baby calf. Another, Feature 335, contained the remains of a juvenile cow skull while Feature 422 had the lower portion of a baby calf. Feature 48 contained the left hind leg and a pelvis of a horse with evidence of pathology on the pelvis. The last burial, Feature 49 contained the elements of two sub-adult cows and a juvenile horse tibia. With the exception of one of the bones in Feature 49 that contained evidence of a tractor impact, none of the bones have been weathered, butchered, or gnawed by predators. Therefore, these mostly represent the remains of articulated burials of farm animals that died at birth or early in their life. The only exception to this is Feature 49 where a juvenile horse tibia was included in the fill along with the remains of two sub-adult cows.

In Midden 1, a total of 42 organic objects was recovered. They consist of 28 botanical remains, 12 shell fragments, and two unidentifiable faunal fragments (Appendix O).

#### **9.4.5 Personal Class**

There are 178 artifacts in the personal class comprising 2.7 percent of the Euro-Canadian assemblage at the site. This includes four adornment items, 56 clothing items, 114 personal gear artifacts, and four toilet/hygiene items (Table 68 and Appendix O).

##### ***Adornment Items***

The adornment items consist of one bead, two pendants, and one pendant chain. The bead is a hexagonal jet bead that is 7.2 mm long and 8.2 mm in diameter (Plate 110). One of the pendants is 24 mm in diameter and is completely corroded. The other pendant is 27.9 mm in diameter and on one side contains an image of a Biblical figure and an inscription “THY DWELLING SHALL BE THE FATNESS OF THE EARTH – GEN – XXVII-29” around the edge. On the other side contains the words “GOOD LUCK” over a horseshoe over the words “FROM/The Farmer’s Advocate/and/HOME MAGAZINE” surrounded by a wreath (Plate 110) (Appendix O). It would appear that this pendant is a complementary gift from *The Farmer’s Advocate and Home Magazine*. The magazine was founded by William Weld in 1866 and become one of the most successful magazines in Canadian history focusing on farming and domestic advice and politically relevant agrarian issues. The magazine lasted until the middle of the twentieth-century (Stewart 2000).

Plate 110: Top. Left, HENDERSON-MONTREAL pipe (Cat. #1328); right, container with a Crown finish (Cat. #1451). Middle. Left, *The Farmer's Advocate and Home Magazine* brass pendant (Cat. #1022); centre, Bank of Upper Canada token (Cat. #1321); right, hexagonal jet bead (Cat. #1257). Bottom. Left, clay marble (Cat. #1329); centre, hand-made spiral glass marble (Cat. #1279); right, heart-shaped plug tobacco tag (Cat. #1280).

Plate 111: Left, jet dress button (Cat. #1347); centre, three-holed bone button (Cat. #1244); right, brass vest button (Cat. #1290). Middle. Left, ceramic shirt button (Cat. #1346); centre, bone outerwear button (Cat. #1276); right, ceramic panty waist button (Cat. #1307). Bottom. Left, thermally altered bone outerwear button (Cat. #1292); centre, rubber coat button (Cat. #1233); right, metal coat button with a mother of pearl inlay (Cat. #1302).

*Clothing Items*

The clothing items consist of one buckle and 55 button fragments (Plate 111). The button fragments represent 54 individual buttons. In total, 16 bone, 15 metal, six shell, 11 ceramic, two jet, one rubber, and three plastic buttons were recovered (Appendix O). These are summarized in Table 73 below.

**Table 73: Buttons from the Mantle site (AlGt-334)**

Cat. #	Provenience	Material	Diameter	Fastener Type	Use	Comments
1226	495N-125E	Shell	8.3 mm	Four holes	Shirt	Possibly child's

Bone buttons were mostly utilitarian in nature primarily intended for men's underwear. They were some of the earliest buttons produced beginning in the eighteenth century, and they started to fall out of popularity by the 1850s. After the 1850s, bone buttons were produced in decreasing numbers until they disappeared in the beginning of the twentieth century (Ferris 1986:100).

Metal buttons were also commercially manufactured beginning in the eighteenth century. Most metal buttons fell out of fashion by the 1830s but utilitarian metal buttons continued to be used throughout the nineteenth century (Ferris 1986:98).

Shell buttons became popular after 1820 and by the 1860s could be made cheaply enough for local entrepreneurs to establish factories. They were worn mostly on shirts and blouses with larger specimens used for waistcoats, frocks, and full-length coats (Ferris 1986:100).

Hand-made porcelain buttons have been used since the eighteenth century but it was not until Richard Prosser patented the machinery in 1840 that ceramic buttons became widely available (Epstein and Saftro 2001:74; Sprague 2002:111). Their manufacture quickly spread to France and the United States in the 1850s and they became extremely affordable. These machine-made prosser buttons were fashionable and readily available between 1850 and 1920 (Luscomb 1967:156) and were used primarily on men's shirts, women's dresses, and children's clothing (Ferris 1986:100). These buttons fell out of manufacture around the 1950s (Sprague 2002).

Rubber buttons were never particularly popular. Patented in 1851 by The Goodyear Novelty Rubber Company, buttons were the only item made of rubber at the time. Rubber buttons were made in a distinctly American monopoly as they were never appreciated by the European market. In Canada they never turn up in great numbers suggesting that this button was never more than a novelty item. They were usually used as cufflinks and occasionally appeared on coats and dresses (Ferris 1986:102).

Finally, plastic buttons are twentieth-century items that completely dominated the button industry by the 1950s (Sprague 2002:115).

### *Personal Gear Items*

The personal gear items consist of one keychain link fragment, two heart-shaped plug tobacco tags (Plate 110), one St. George token, and 110 smoking pipe fragments. The token is 33.3 mm in diameter. On one

side it depicts St. George slaying the dragon with the words “BANK OF UPPER CANADA/1852” written around the perimeter. The reverse displays a crown over a crossed anchor and sword over two cornucopias; the words “BANK TOKEN/ONE PENNY” are written around the perimeter (Plate 110) (Appendix O).

The use of tobacco tags began in the United States in the 1870s where they were developed to prevent unscrupulous individuals from selling the cheaper product as a higher grade variety. Originally these were wooden but quickly disappeared with the advent of tin tags prior to 1880. Inexpensive to produce, tags quickly spread and over 12,000 different tags were in circulation. In Canada, the heart shaped tobacco tags were a trademark seal of W.C. MacDonald Inc. of Montreal between 1870 and 1922. They were pressed into each plug of chewing and smoking tobacco and these tags became extremely common in Canada (Springate 1997).

The smoking pipes consist of 48 bowl fragments, six mouthpiece fragments, and 56 stem fragments. Out of the stem fragments, ten had identifiable maker’s marks (Plate 110) (Appendix O). These are summarized in Table 74 below.

**Table 74: Dateable Euro-Canadian Pipes from the Mantle site (AlGt-334)**

Cat. #	Provenience	Maker’s Mark	Date*
1242	496N-122E	MURRAY/GLASGOW	1833 – 1861
1278	497N-124E	MURRAY/GLASGOW	1833 – 1861
1358	499N-133E	MCDUGALL/GLASGOW	1846 – 1967
1241	496N-122E	HENDERSON/MONTREAL	1847 – 1876
1269	497N-122E	HENDERSON/MONTREAL	1847 – 1876
1285	497N-125E	HENDERSON/MONTREAL	1847 – 1876
1328	499N-120E	HENDERSON/MONTREAL	1847 – 1876
1350	499N-125E	HENDERSON/MONTREAL	1847 – 1876
1284	497N-125E	DAVIDSON/GLASGOW	1861 – 1910
1270	497N-122E	BELL/QUEBEC	1862 – 1881

\*All dates are derived from Kenyon 1984 and Walker 1971

The identifiable maker’s marks on pipe stems conform to the date range for the Euro-Canadian component established with diagnostic ceramics.

### *Toilet/Hygiene*

The toilet and hygiene items consist of two creamware chamber pot sherds, including a very large rim (Plate 112), and two bone comb fragments with teeth on two sides (Appendix O). The presence of creamware chamber pot sherds should not be used as an indicator of an earlier date for the Euro-Canadian component of the site. As George Miller notes, plain creamware continued to be used for chamber pots into the 1850s (Miller 1993).

Plate 112: Creamware chamber pot  
(Cat. #2493).

#### 9.4.6 Tools/Equipment Class

There are 126 artifacts associated with the tools and equipment class comprising 1.9 percent of the Euro-Canadian component of the site. The class consist of 38 animal husbandry items, eight armament items, one general tool, 62 pieces of hardware, two musical artifacts, two recreation artifacts, seven sewing objects, three specialized tools, and three writing objects (Table 68 and Appendix O).

The animal husbandry items consist of four harness buckles, one horse halter, and 33 horse shoe nails. The armament items consist of seven .22 calibre shell casings and one .38 calibre shell casing. The general tool is an indeterminate tool fragment with a threaded haft end and a portion of a blade. Hardware consists of one angle iron, two bolts, two chain links, nine clothes pin springs, two fence staples, 20 fence wires, one flywheel, one nail punch, two O-rings, three rivets, eight screws, one spike, three pieces of strapping, two tacks, and five washers. Four straight pins and three adult thimbles make up the sewing objects. One chisel and two whet stones comprise the specialized tools and three slate pencils represent the writing objects (Appendix O).

The musical category consists of a bone tuning peg for a musical instrument and a mouth harp (Appendix O). The mouth harp is a plucked idiophone that is capable of producing only one note. The harmonics of this note can be modified by altering the resonance pattern created by various shaping's of the cavities of the mouth and tongue (Kenyon 1987b). The one recovered from the Mantle site has a round, oval frame.

Recreation items consist of two marbles (Appendix O). One of the marbles is made from clay and is 17.3 mm in diameter while the other is a hand-made spiral glass marble that is 13.5 mm in diameter (Plate 110). Clay marbles have existed for thousands of years and fell out of production by the 1940s while hand-made spiral glass marbles were produced between 1845 and 1920 (Kenyon 1987a).

#### 9.4.7 Indeterminate Class

In the Euro-Canadian assemblage from the site, there are 239 artifacts that could not be assigned to a functional class. These consist of 208 unidentified container glass fragments and 31 other unidentifiable items (Table 68 and Appendix O). Among these, two Crown bottle finish fragments were recovered from Midden 1 (Plate 110). The Crown finish was patented in the United States in 1892 and was used extensively for beer, soft drink, and mineral water bottles (Jones and Sullivan 1989:79).

### 9.5 EURO-CANADIAN COMPONENT INTERPRETATION AND CONCLUSION

The excavations at the site identified the remains of nineteenth-century Euro-Canadian occupation of Lot 33, Concession 9. This occupation can be divided into two components. The first component consists of the late-nineteenth/early-twentieth century farmhouse and barn foundations, two middens, and 25 non-Iroquoian features. The second component consists of early-to-mid nineteenth-century remains from a block-excavated Midden 1 area. A total of 6,612 Euro-Canadian artifacts was recovered.

The features in the first component consisted of five farm animal burials and several miscellaneous features that probably related to the late-nineteenth/ twentieth-century operations of the barns and the farmhouse. Midden-like concentrations #2 and #3 contained only a few other Euro-Canadian artifacts that were recovered in a re-deposited context from the demolition of the Mantle farmhouse. Given this, the only significant, *in situ*, nineteenth-century material was recovered from the second component, Midden 1.

To place Midden 1 within the historical land use context, research was conducted at the Ontario Archives. According to the *Abstract Index of Deed titles*, the Crown Patent for all 200 acres of Lot 33, Concession 9, was issued to Graney Curtis in 1802 which was then sold to Simon Morton in 1808. That same year, the land was sold to Jonas Byers who then sold it to Samuel Byers in 1836. Much of the land remained in the possession of the Byers (also spelled Boyer) family until the turn of the century.

According to Walton's 1837 *Home District Directory* and the 1846 Brown's *Home District Directory*, Samuel Byers occupied the property in the first half of the nineteenth century. In the 1851 and 1861 censuses, James Bugg and his family were enumerated for the property. They lived in a two-storey brick house and operated a saw mill on the property. Lot 33, Concession 9 was absent from the agricultural returns in the 1871 and 1901 census which may indicate that land stopped being farmed, or even occupied, in favour of the milling operation. While it cannot be confirmed because Lot 33, Concession 9 was not entered on Schedule 3 of the 1871 census, it is possible that by 1871 the water mill was augmented with a back-up steam power source and was operated by Edward Wheeler. The mill appeared on an 1878 map for the area. Milling on the property ceased sometime around 1911.

The artifacts recovered from Midden 1 indicate that the area was utilized for the disposal of garbage between the 1830s and the 1870s. It is interesting to note that the Midden 1 assemblage is characterized by a large amount of domestic items that would not be expected if the area was utilized exclusively for refuse from a mill. While personal items such as buttons and smoking pipes and food consumption items like tableware and teaware are bound to be recovered from the use and discard by mill workers, the sheer quantity of domestic material suggests that the area became a midden for domestic refuse and was used until the last quarter of the nineteenth century.

Hand-wrought nails and early ceramic types like creamware and pearlware along with a large amount of mid-nineteenth-century items indicates that the area was utilized during both Jonas and Samuel Byers' and James Bugg's occupation of the property. Given that garbage was usually discarded directly behind the house during the nineteenth century (MacDonald 1997), it is likely that the original nineteenth-century farmhouse was located near Midden 1. This, along with the similarity between the farmhouse that was demolished in 2002 and the house James Bugg was enumerated in along with the proximity between the former farmhouse and the house marked on the 1860 *Tremaine* map suggests that the former farmhouse marks the location of the original brick 1851 farmhouse. While the stylistic details of the former farmhouse and the background information supplied by Stanley Mantle suggest that the house was built in the 1880s or 1890s, it is probable that the original brick farmhouse was either demolished and a new building was built on its foundation or that the old house was completely refurbished and incorporated into the new.

Stanley Mantle's account of the 1880s and 1890s construction/refurbishment coincides with evidence from both the archaeological record and the archival history. As noted earlier, neither Lot 33 nor James Bugg are listed in the 1871 census schedules suggesting that the land was leased to a different party, possibly Edward Wheeler, and both the house and milling operation were refurbished. The amount of diagnostic artifacts also dropped off after the 1870s indicating a shift in house function, a shift in the refuse disposal pattern, or both. It is possible that either the house ceased to be used for domestic purposes or the midden shifted further away to subscribe to the late nineteenth-century refuse disposal pattern of a "back forty" dump (MacDonald 1997:60). Such shifts in land use stemming from changes in land ownership have previously been observed in other archaeological contexts (Groover 2003).

It should be noted that the artifact class percentages recovered from Midden 1 do not coincide with what has been previously observed for domestic middens in Southern Ontario (MacDonald 1997).

Architectural artifacts from Midden 1 were significantly greater than what has been observed on rural domestic sites indicating that the Euro-Canadian component here was formed by a different process. This process relates to Midden 1's close proximity to the mill and one of the ancillary mill buildings whose

foundation was uncovered during the excavation. While the function of this structure is unknown, based on historical photographs it existed in the early twentieth century as part of the milling complex. The presence of the building and the shift in refuse disposal at the end of the nineteenth century may explain why a large number of architectural items is present in the Euro-Canadian artifact assemblage. The abandonment and the demolition of the mill and its ancillary buildings in the early twentieth century would have produced a great deal of architectural material.

To summarize, the Stage 4 mitigative excavation of the Mantle site exposed remnants of the Euro-Canadian occupation of the property. These remnants could be separated into two components. The first consisted of a few re-deposited artifacts from the demolition of the late nineteenth-century farmhouse, a number of miscellaneous features, and five animal burials around a pair of late nineteenth/early twentieth-century barns. This post-1870 component does not represent a significant cultural resource as per the Ministry of Tourism, Culture, and Sport's Standards and Guidelines for Consultant Archaeologists (MTCS 2011:59).

The second component consists of a variety of early-to-mid nineteenth-century artifacts recovered from the block excavated Midden 1 area, approximately 85 metres to the northeast of the barn features. This area is in close proximity with a former mill complex that stood on the property between circa 1851 and 1911 and the location of a mid-nineteenth-century farmhouse. Based on the criteria established by the Ministry of Tourism, Culture, and Sport (MTCS 2011:59), this is a significant cultural resource and the Euro-Canadian artifacts recovered from this component help to inform our understanding of the early cultural and industrial history of Markham Township. Midden 1 and the mill are outside of the development given their presence within a protected zone. As Midden 1 and the mill are not subject to development, these Euro-Canadian cultural heritage resources should be protected from future soil alteration activities.

## 10.0 SUMMARY AND CONCLUSIONS

Ronald Williamson, Jennifer Birch, Andrea Carnevale and Andrew Clish

Archaeological Services Inc. was contracted by Lebovic Enterprises to conduct a Stage 3-4 archaeological investigation of the Mantle site (AlGt-334), located on part of Lot 33, Concession 9, in the former Township of Markham, now the Town of Whitchurch-Stouffville, Regional Municipality of York Ontario.

The Mantle site was a plough-disturbed ancestral Wendat village ranging between 2.0 and 2.9 hectares in size and comprised a total of 98 longhouses within a series of palisade walls, which appear to have been contracted at least three times, the latter of which involved the construction of a refuse-filled borrow trench adjacent to the palisade suggesting the former presence of an earthworks. Although there is clear evidence of continual modification of longhouses, the analysis of the settlement patterns suggests a contracting community consisting of an early and a late phase, each consisting of many years. The east-west pattern of longhouse orientation in the northern half of the site was maintained in both phases, along with two structures thought to have been occupied by chief's lineages. The radial pattern in the southern half in the early phase is replaced by a more haphazard arrangement of houses in the late phase. Analyses of the built environment of the site have yielded insights into how people constructed, inhabited and negotiated both domestic and public spaces and indicate that detailed intra-site analyses are helpful in identifying the small-scale changes in practice that reflect the lived experience of coalescence communities (see Birch 2010, 2012 and Birch and Williamson 2013 for a more detailed analysis of the place of Mantle in the development of coalescent ancestral Wendat villages along the north shore of Lake Ontario).

A total of 1,415 subsurface cultural features was recorded, both within and exterior to the house structures. Five separate exterior activity areas were identified, including an east-central "plaza" area that appears to have been used in the early phase of the site. This plaza area includes many large refuse and ash-filled depressions, and this space may have provided a venue for communal events such as feasts and ceremonies while increasing visibility between houses.

Based on the analysis of material culture collected during the excavations, it is suggested that the site was occupied around the turn of the sixteenth century. Two radiocarbon dates on carbonized maize kernels (Table 75), together with ceramic seriation indicate that the site was likely occupied in the early sixteenth century, which is consistent with the settlement pattern data. While admittedly provisional at best due to the problem of multiple intercepts at this general time period, these dates can be interpreted to be consistent with the period during which we believe the site was occupied.

**Table 75: Radiocarbon dates on carbonized maize kernels**

Site Name, <sup>14</sup> C Lab No., Sample	<sup>14</sup> C Yrs I σ B.P.	δ <sup>13</sup> C‰	cal A.D. Yrs (1σ)	cal A.D. Yrs (2σ)
Mantle site, Beta-217158, carbonized maize	340 I 40	-9.6	1487 - 1527 (0.34) 1554 - 1604 (0.44)	1462 - 1642 (0.95)
Mantle site, Beta-217159, carbonized maize	370 I 40	-7.6	1453 - 1521 (0.67)	1446 - 1530(0.53) 1539 - 1635(0.47)

The recovered material culture included a modest assemblage of flaked lithics, and a considerable number of ground stone tools, especially celts many of which had been thermally altered but also a number of discoidal steatite beads. The ceramic assemblage included a variety of vessels, largely featuring incised decorations on the collars and plain necks but also types and attributes that point to links between the

community and Iroquois populations to the south (e.g., Oneida castellation effigies) and populations to the east in the St. Lawrence Valley (e.g., corn-eared). The pipe complex features predominantly ring barrel types along with a considerable number of coronet pipes. Several anthropomorphic and zoomorphic effigies were also recovered. The recovered bone tools included beads, awls, pendants and an antler comb. Two native copper and two European copper artifacts were recovered along with a fragment of an iron tool thought to have been forged in the Basque region of Spain and traded to St. Lawrence Iroquoians who may have acquired the piece, either directly or indirectly, from Red Bay on the Strait of Belle Isle. It is the earliest piece of European iron currently known in the Great Lakes Region. The material culture in some ways reflects the creation of new community-based identities, especially in the appearance of links to the south and east and in the adoptions of steatite pendants and beads rather than the pebble pendants worn by people in the previous decades.

The plant and animal remains from the site suggest an economy typical of Iroquoian peoples at this time, consisting of the cultivation of maize, beans, squash, sunflower and tobacco, supplemented with the collection of wild plants, mainly fleshy fruits. Wood charcoal analyses were used to explore differences in building habits in the early versus late phases of the site, but no statistically significant differences were observed — mainly maple and beech were used, likely felled during clearing of the corn fields surrounding the village. Faunal remains included both small and large mammals, fish and birds, with the bones of some used for tools. Compared to other ancestral Wendat communities on the south slope, however, the Mantle inhabitants do not appear to have expended much effort on the lake fishery favouring instead the hunting of deer, perhaps predominantly to secure the large numbers of deer hides they would have required to cloth themselves. Indeed, the site data suggest that the acquisition of hides for clothing may have presented a unique and pressing challenge for such a large population and the hide requirements of the community may not have been met locally, all of which may have significant implications for fifteenth-century conflict and the extension of trading networks with both their Iroquoian and Algonquian neighbours (see Birch and Williamson 2013 for a more detailed treatment of the implications of the site economy).

The Mantle project began as a routine cultural resource management project and quickly evolved into a multi-year analysis in which ASI involved the descendants of the past we were investigating. While our team had worked very closely with the Huron-Wendat Nation of Wendake, Quebec for the past several years on this project, a particularly significant event occurred in the early fall of 2011 when a ceremony was held at which time the village and cemetery was renamed Jean-Baptiste Lainé, in honour of a late Wendat community elder. In recognition of their local history, a nearby elementary school in Stouffville has been named “Wendat Village School.”

The excavation of the site also exposed remnants of the Euro-Canadian occupation of the property. These remnants could be separated into two components. The first consisted of a few re-deposited artifacts from the demolition of the late nineteenth-century farmhouse, a number of miscellaneous features, and five animal burials around the late nineteenth/early twentieth-century barns. The second component consists of a variety of early-to-mid nineteenth-century artifacts recovered from the block excavated Midden 1 area. This area is within or adjacent to one of the buildings of the former mill complex that stood on the property between circa 1851 and 1911. This is a significant cultural heritage resource and the Euro-Canadian artifacts recovered from this component have helped to inform our understanding of the early cultural and industrial history of Markham Township.

Since the completion of the Mantle site excavations in 2005, the subdivision development that necessitated the work in the first place has been completed.

## 1.0 INTRODUCTION

Archaeological Services Inc. was contacted by Sernas Associates on May 10, 2006 when evidence of human remains was discovered during construction activities to the southwest of the Mantle site (AIGt-334), in the valley lands located between the site and Stouffville Creek (Figure 1). Mr. Martin Cooper, Mr. Andrew Clish, and Ms. Kristine Crawford of Archaeological Services arrived at the scene in the morning to investigate the findings.

Upon arrival at the site, ASI staff was directed to the human remains, which were discovered in a drainage ditch approximately 20 metres in length. ASI was informed that this ditch had been trenched in late October of 2005 in order to alleviate drainage of the area of the proposed SWM pond. In the spring of 2006 the area to the west of this ditch was bulldozed in preparation for a service corridor. It was during this phase of construction activities that the remains were discovered in the bank and along the floor of the ditch. Authorities were subsequently notified.

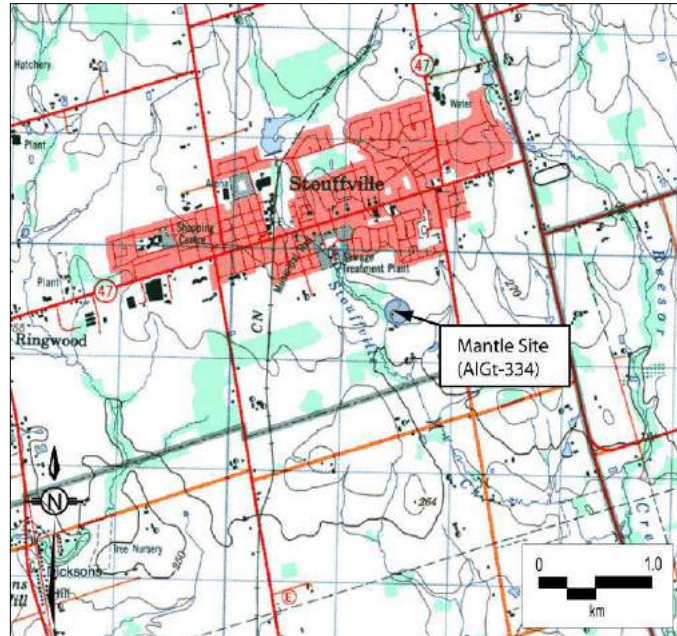

Figure 1: Location of Study Area

NTS 30 M/14

The investigation was conducted under the project management of Dr. Ron Williamson, under archaeological license (P046) issued to Mr. Andrew Clish in accordance with the Ontario Heritage Act (1990). Permission to access the study area and undertake all activities required to conduct this investigation was granted to Archaeological Services Inc. by Stouff Con Ten Holdings Limited.

An earlier version of this report was submitted to the Registrar of Cemeteries, Ministry of Consumer and Business Affairs, in fulfilment of Section 70 of the Cemeteries Act (1990). This report represents the fulfillment of the 2006 licensing agreement with the Ontario Ministry of Culture and the statements contained on the CIF P046-044 (Clish). The Mantle site burials (AIGt-334) on the subject property have been investigated, documented, and protected in the manner agreed upon in a disposition agreement subsequently established between the landowner, the Cemeteries Registrar, and relevant First Nations.

## 2.0 BACKGROUND OF THE MANTLE SITE (AIGt-334)

The presence of a large Late Iroquoian site on the east half of Lots 32 and 33 was originally reported to ASI personnel during work on the Ninth Line Sanitary Trunk Sewer Extension to Stouffville (ASI 2002). This settlement was previously unknown to archaeological researchers. ASI was subsequently retained by Lebovic Enterprises to undertake further investigation of the site, resulting in the preliminary definition of

the character and extent of the Iroquoian settlement, which was subsequently registered as the Mantle site (AlGt-334).

The plough-disturbed sixteenth century Late Woodland Mantle site (AlGt-334) occupies a broad promontory on the east side of Stouffville Creek, encompassing an area of 4.2 hectares. The original documentation of the site and an account of our preliminary investigations are provided in two previous reports: *Stage 1 and 2 Archaeological Assessment of the Lebovic-Stouffville Development, Part of Lots 32, 33, and 34, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario* and *Investigation of the Mantle Site (AlGt-334) Part of Lot 33, Concession 9, Town of Whitchurch-Stouffville, Regional Municipality of York, Ontario, Preliminary Report*.

Stage 4 salvage excavations at the site took place between the late summer of 2003 and mid-autumn of 2005. The initial task in the Stage 4 excavation entailed use of a Gradall to excavate a series of trenches to identify the full limits of the site on the table lands that are subject to development. In this operation, the ploughzone, consisting of roughly 30 centimetres of topsoil, was removed to reveal the subsoil and all potential features and post moulds were further examined through shovel-shining and trowelling. This activity was supervised by Mr. Andrew Clish, and only conducted in weather that ensured suitable visibility and lighting. An area of approximately 6300 m<sup>2</sup> was exposed in this manner, resulting in the exposure of two sets of palisades on the northern, eastern and southern peripheries of the site together with a longhouse and ancillary features. The inner palisades were found to consist of three to five rows of large, closely spaced posts, while the outer palisades are represented by two rows.

Once the limits of the site were established, attention was shifted to the interior of the site, first focusing upon the area of the storm water management pond, which comprised the southern half of the settlement. The removal of plough zone within this area was preceded by completion of the controlled surface collection in those areas that had not been ploughed earlier during the preliminary investigations. Test units were also excavated in areas of high surface artifact concentrations in order to detect and sample any ploughed out midden deposits that may have been present. In 2005, the excavation of the north half of the site was undertaken and completed in the fall of that year.

Overall, approximately 100,000 artifacts were recovered from the site, and 73 longhouses of various sizes and orientations were uncovered within the excavated portion of the settlement. Substantial areas adjacent to the top of bank were disturbed as result of the previous construction and subsequent demolition of a barn and outbuilding, a process which involved razing of the buildings, deep excavations, as well as bulldozing and stockpiling of large quantities of the associated structural debris and earth. Similar disturbances, on a smaller scale, were associated with the demolition of the farmhouse on the northwest side of the site adjacent to the creek valley. On the other hand, intact deposits relating to the site remain extant in the northwest sectors valley lands.

## **2.1 INITIAL CEMETERY INVESTIGATION**

ASI was contacted on May 10, 2006, to investigate the discovery of human remains in an area near the Mantle site (AlGt-334). Upon arrival at the scene, and after initial inspection of the site, ASI immediately contacted Mr. Michael D'Mello, Registrar of the Cemeteries Section of the Ministry of Consumer and Business Services. The Stouffville detachment of the York Regional Police was also informed of the discovery, who in turn notified the coroner. After the investigation by the police and coroner determined

that the area did not constitute a crime scene, the site was turned over to the Registrar of Cemeteries. Pursuant to Section 70 of the Cemeteries Act (R.S.O. 1990), the development proponent was asked by Mr. D'Mello to conduct an investigation of the remains such that the origin of the burial site could be ascertained and a site declaration issued by the Registrar. ASI was asked by Stouff Con Ten Holdings Limited to conduct this investigation.

The remains that were initially found included a partial cranium in the bank of the ditch, as well as several cranial and postcranial elements along the floor of the ditch (Plate 1). Upon initial inspection, it appeared that the burial of a single individual had been impacted by the trenching, with most of the cranium left intact and all postcranial material removed. A single discoidal shell bead (Plates 2 and 3) was discovered with this cranium located in the bank. When the trench was excavated, the fill from the trench was placed on a small strip of land to the south, between the trench and the silt fencing edging the south boundary of the property. This fill, along with the north and south banks of the trench, was visually inspected for human remains, and all elements were marked with flags.

The area to the west of the trench had been graded by a bulldozer and all topsoil removed to a depth of approximately 30 centimeters below sod (Plates 4 and 5). The cut face of this graded area was visually inspected, and during this investigation, evidence of what appeared to be two crania, approximately 30 centimetres apart, was discovered. The surface of the graded area, as well as the fill which was deposited to the north of the graded area, was carefully walked in half metre intervals, and all bone was marked accordingly.

By looking at the cranial elements of both the in-situ and surface remains, a minimum number of individuals (MNI) count indicated the presence of at least five individuals. This MNI, in conjunction with the close proximity of the Mantle site (AlGt-334) and the finding of the shell bead, led to the determination that the area constitutes an aboriginal burial ground associated with that site.

All in-situ remains were marked and covered with filter cloth and soil. Temporary fencing was erected under the direction of ASI staff around the perimeter of the area in which human remains had been recovered to ensure adequate protection of the remains and any associated artifacts.

### **3.0 FURTHER INVESTIGATION AND FIELD METHODS**

ASI crew began work at the site on May 30 2006 in order to determine the type and extent of the burial ground. Upon arrival at the site, it was noted that there had been some hand shoveling activity along the banks of the drainage trench. As security of the site seemed to be an issue, a security guard was provided during the evenings and on weekends to maintain the integrity of the site and protection of the burials.

The entire area was walked in half-metre intervals, with all surface bone marked, mapped using a transit<sup>1</sup>, and collected (Figure 2). During this procedure, evidence of another in-situ cranium was found in the southern graded area. As there was now evidence of at least three intact burials, it was decided that two metre test units would be placed over these crania in order to determine if these remains constituted primary interments. Units were placed in the following areas: one unit over the cranium in the graded

---

<sup>1</sup> All recording during the detailed site investigations was provenienced relative to the grid system utilized at the Mantle site.

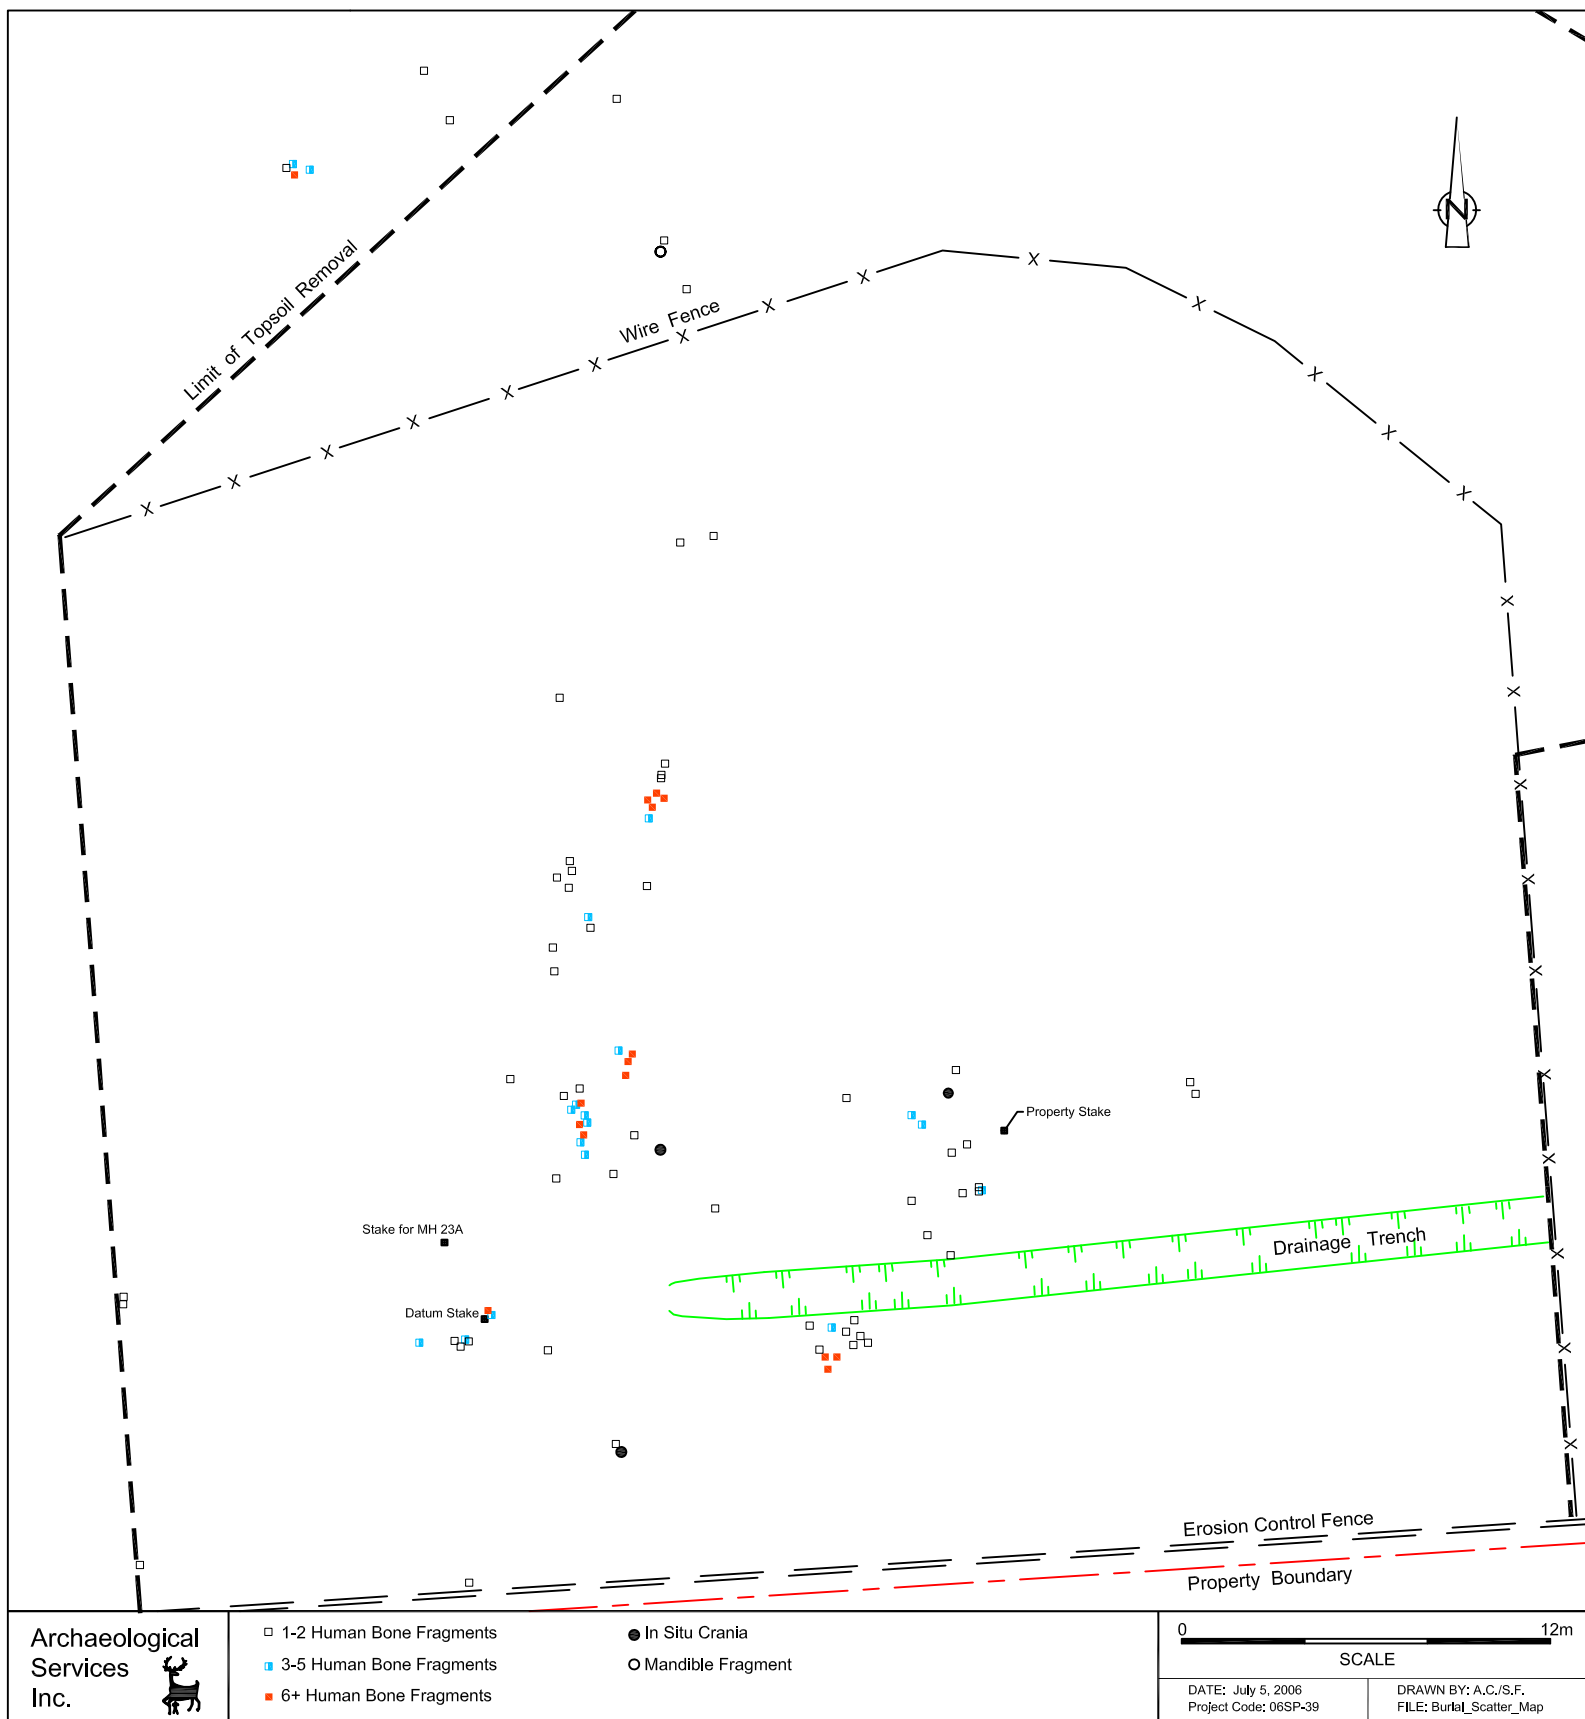

Figure 2: Controlled Surface Collection of the Mantle Site (AIGt-334)

area, one unit over the two possible crania in the eastern bank of the graded area, and a unit near the original findspot in the drainage trench (Figure 3). The soil in each unit was carefully removed by hand trowelling along with the use of wooden tools and brushes, to be replaced over the burial after recording and photography.

When excavated, the units resulted in the exposure of three intact, primary burials. The unit over what were thought to be two crania revealed that these were intact related to a single adult individual, the pelvis having been mistaken for a cranium. Burial 1, an adult, was oriented head to the north facing the east, and was very tightly flexed, with both arms crossed underneath the torso, hands on either side of the face. Burial 2, also an adult, was oriented head to the south, facing east, and was in a semi-flexed position. Burial 3, a subadult, was oriented head to the northeast and face to the northwest, with hands together in front of the face. Two of these burials also had associated artifacts: a bone bead above the cranium of Burial 2; and a bone bead at the ear of Burial 3. These artifacts remain in-situ with these burials.

In order to determine the extent of the burial ground, the surrounding topsoil was removed by the use of a Gradall supervised by Mr. Andrew Clish, and conducted only during suitable weather conditions. This activity was also monitored by a designated representative of the Wendat (Hurons of Wendake/Lorette), who continued monitoring throughout various stages of the project. During topsoil removal, it was noted that large portions of the area were full of large rocks and rubble. It is likely that at least a portion of the rocks were deposited there by previous farming operations. Portions of this area were also clearly disturbed by previous activities, with fragments of metal, plastic, and historic faunal materials observed but not retained. In the eastern area of the site the soil was sandy gravel, topped in sections with thick clay and rock, while the west half of the site was clay. During soil removal there was no visual evidence of pits or staining before encountering a burial, however, the soil in the eastern area often changed to a sandier matrix.

The soils that had been previously disturbed by the trenching and bulldozing activities were also stockpiled by the Gradall prior to further topsoil removal. A portion of the trench backdirt as well as the primary burial area backdirt was screened with the use of a mechanical screen with ¼ inch mesh in order to recover any disturbed remains and associated artifacts.

While the Cemeteries Act requires that a distance of five metres be stripped beyond a burial, in this case the topsoil was removed to a minimum of 15 metres beyond a burial, as several of the burials were found roughly 9 meters apart.

A total of 37 interments (Figure 4) was found clustered in an area below the top of slope in the valley lands. Of these burials, 31 were adults, two were adolescents, and five were infants / juveniles. In order to establish if there were any patterns present, 19 of these burials were partially exposed using wooden tools and brushes, photo documented, and hand drawn. Two of these burials were bundles: Burial 7 comprised two adult individuals; and Burial 17 one adult individual. Burial 8 was a subadult deliberately covered with a layer of large rocks. The orientations of the burials vary from head to the north, northeast, south and southeast. The burials were also seen to be bundled, tightly flexed, and semi-flexed.

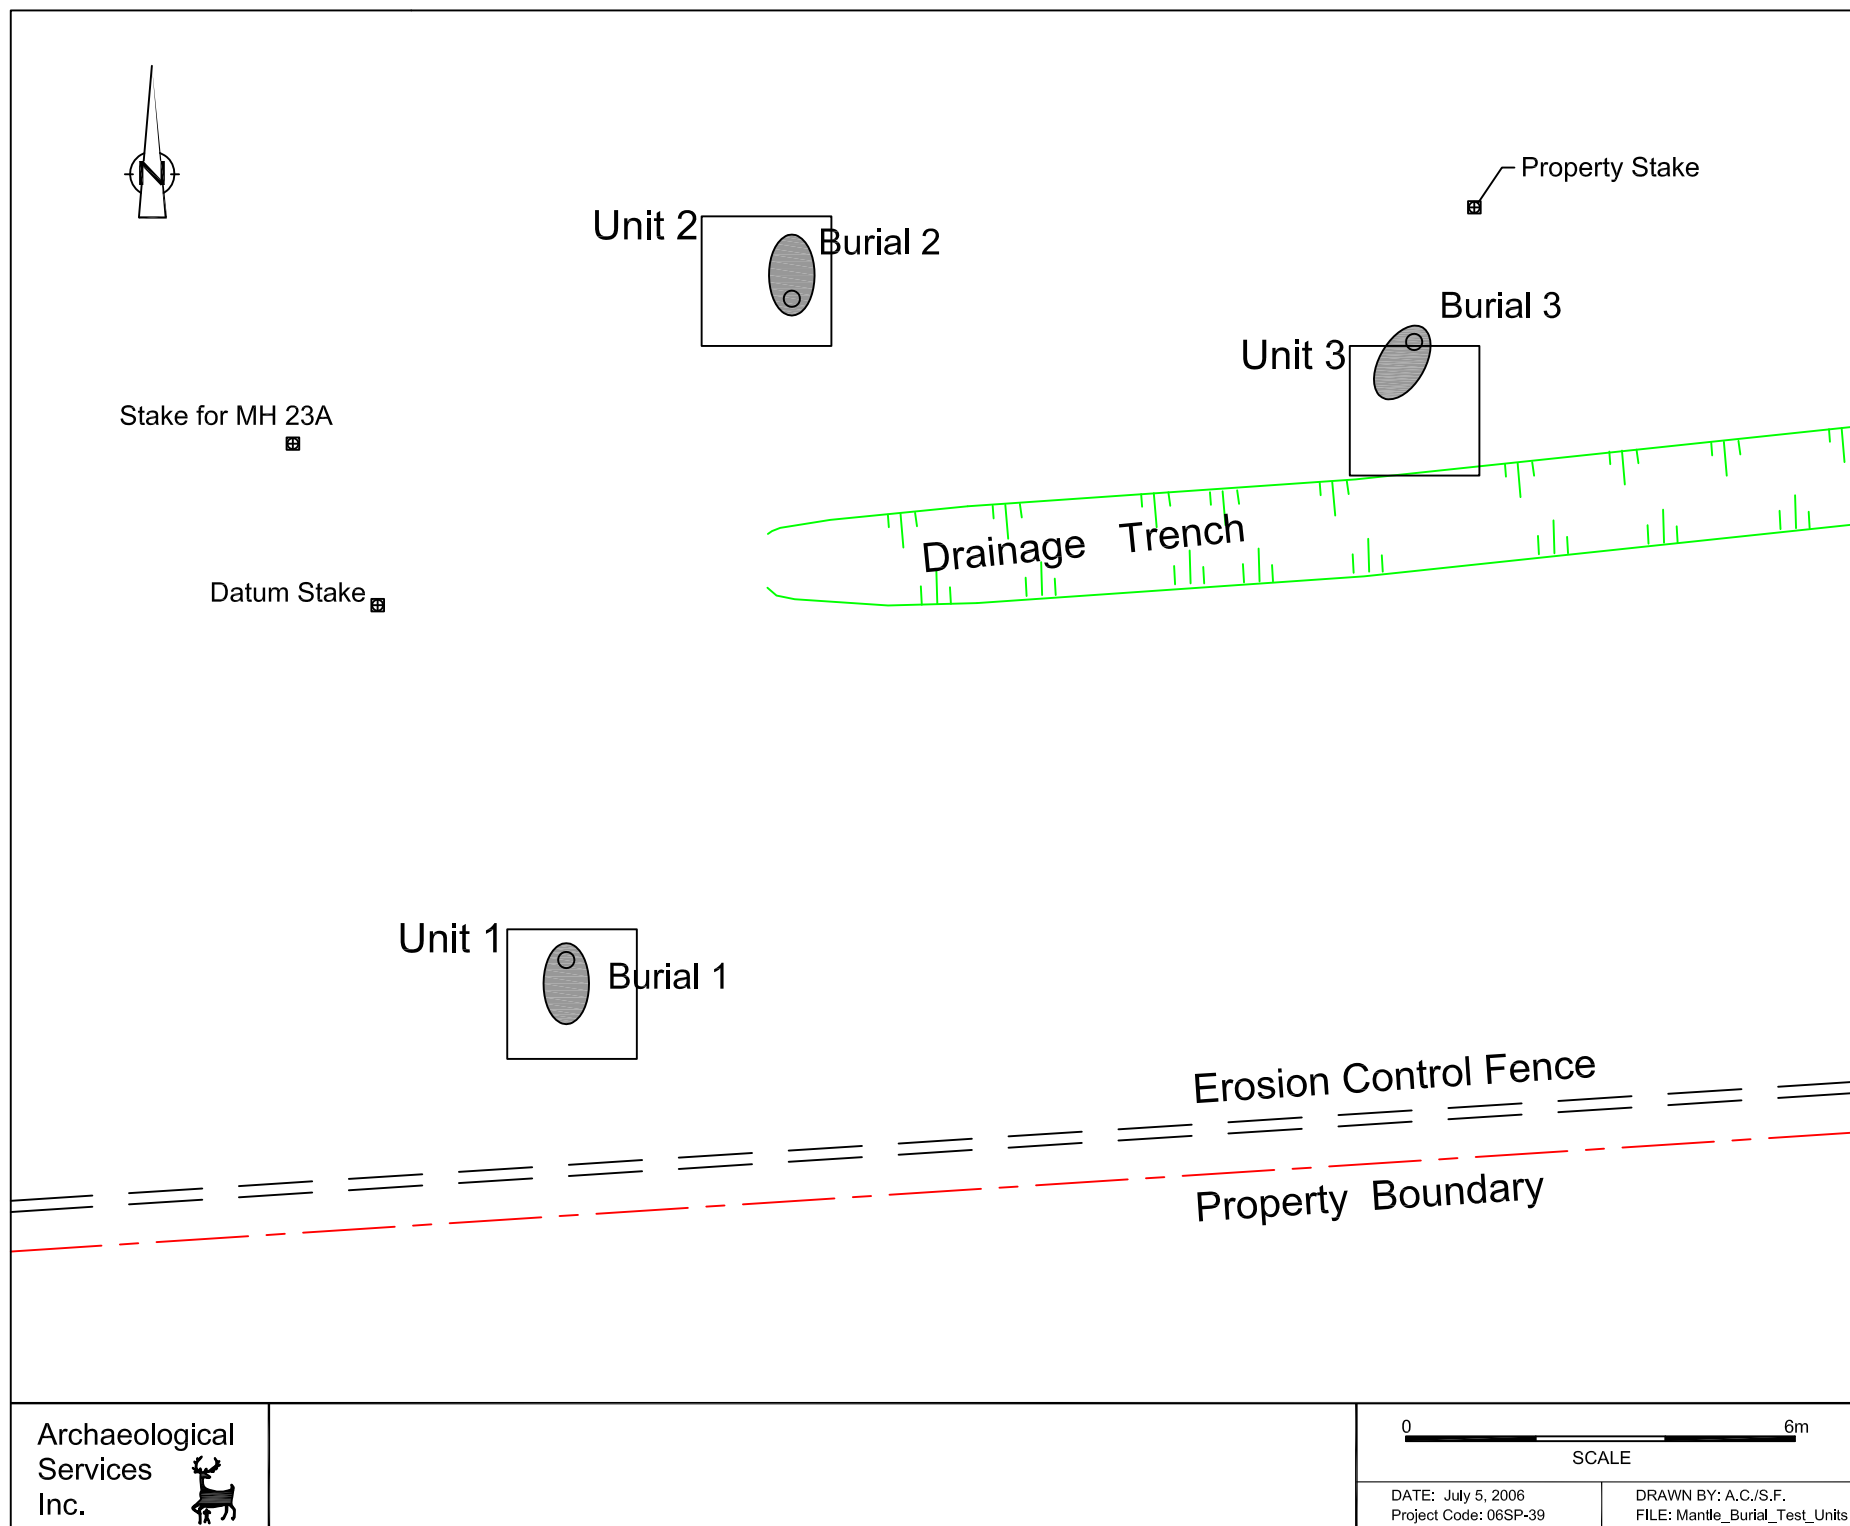

Figure 3: Test Units of the Mantle Site (AIGt-334)

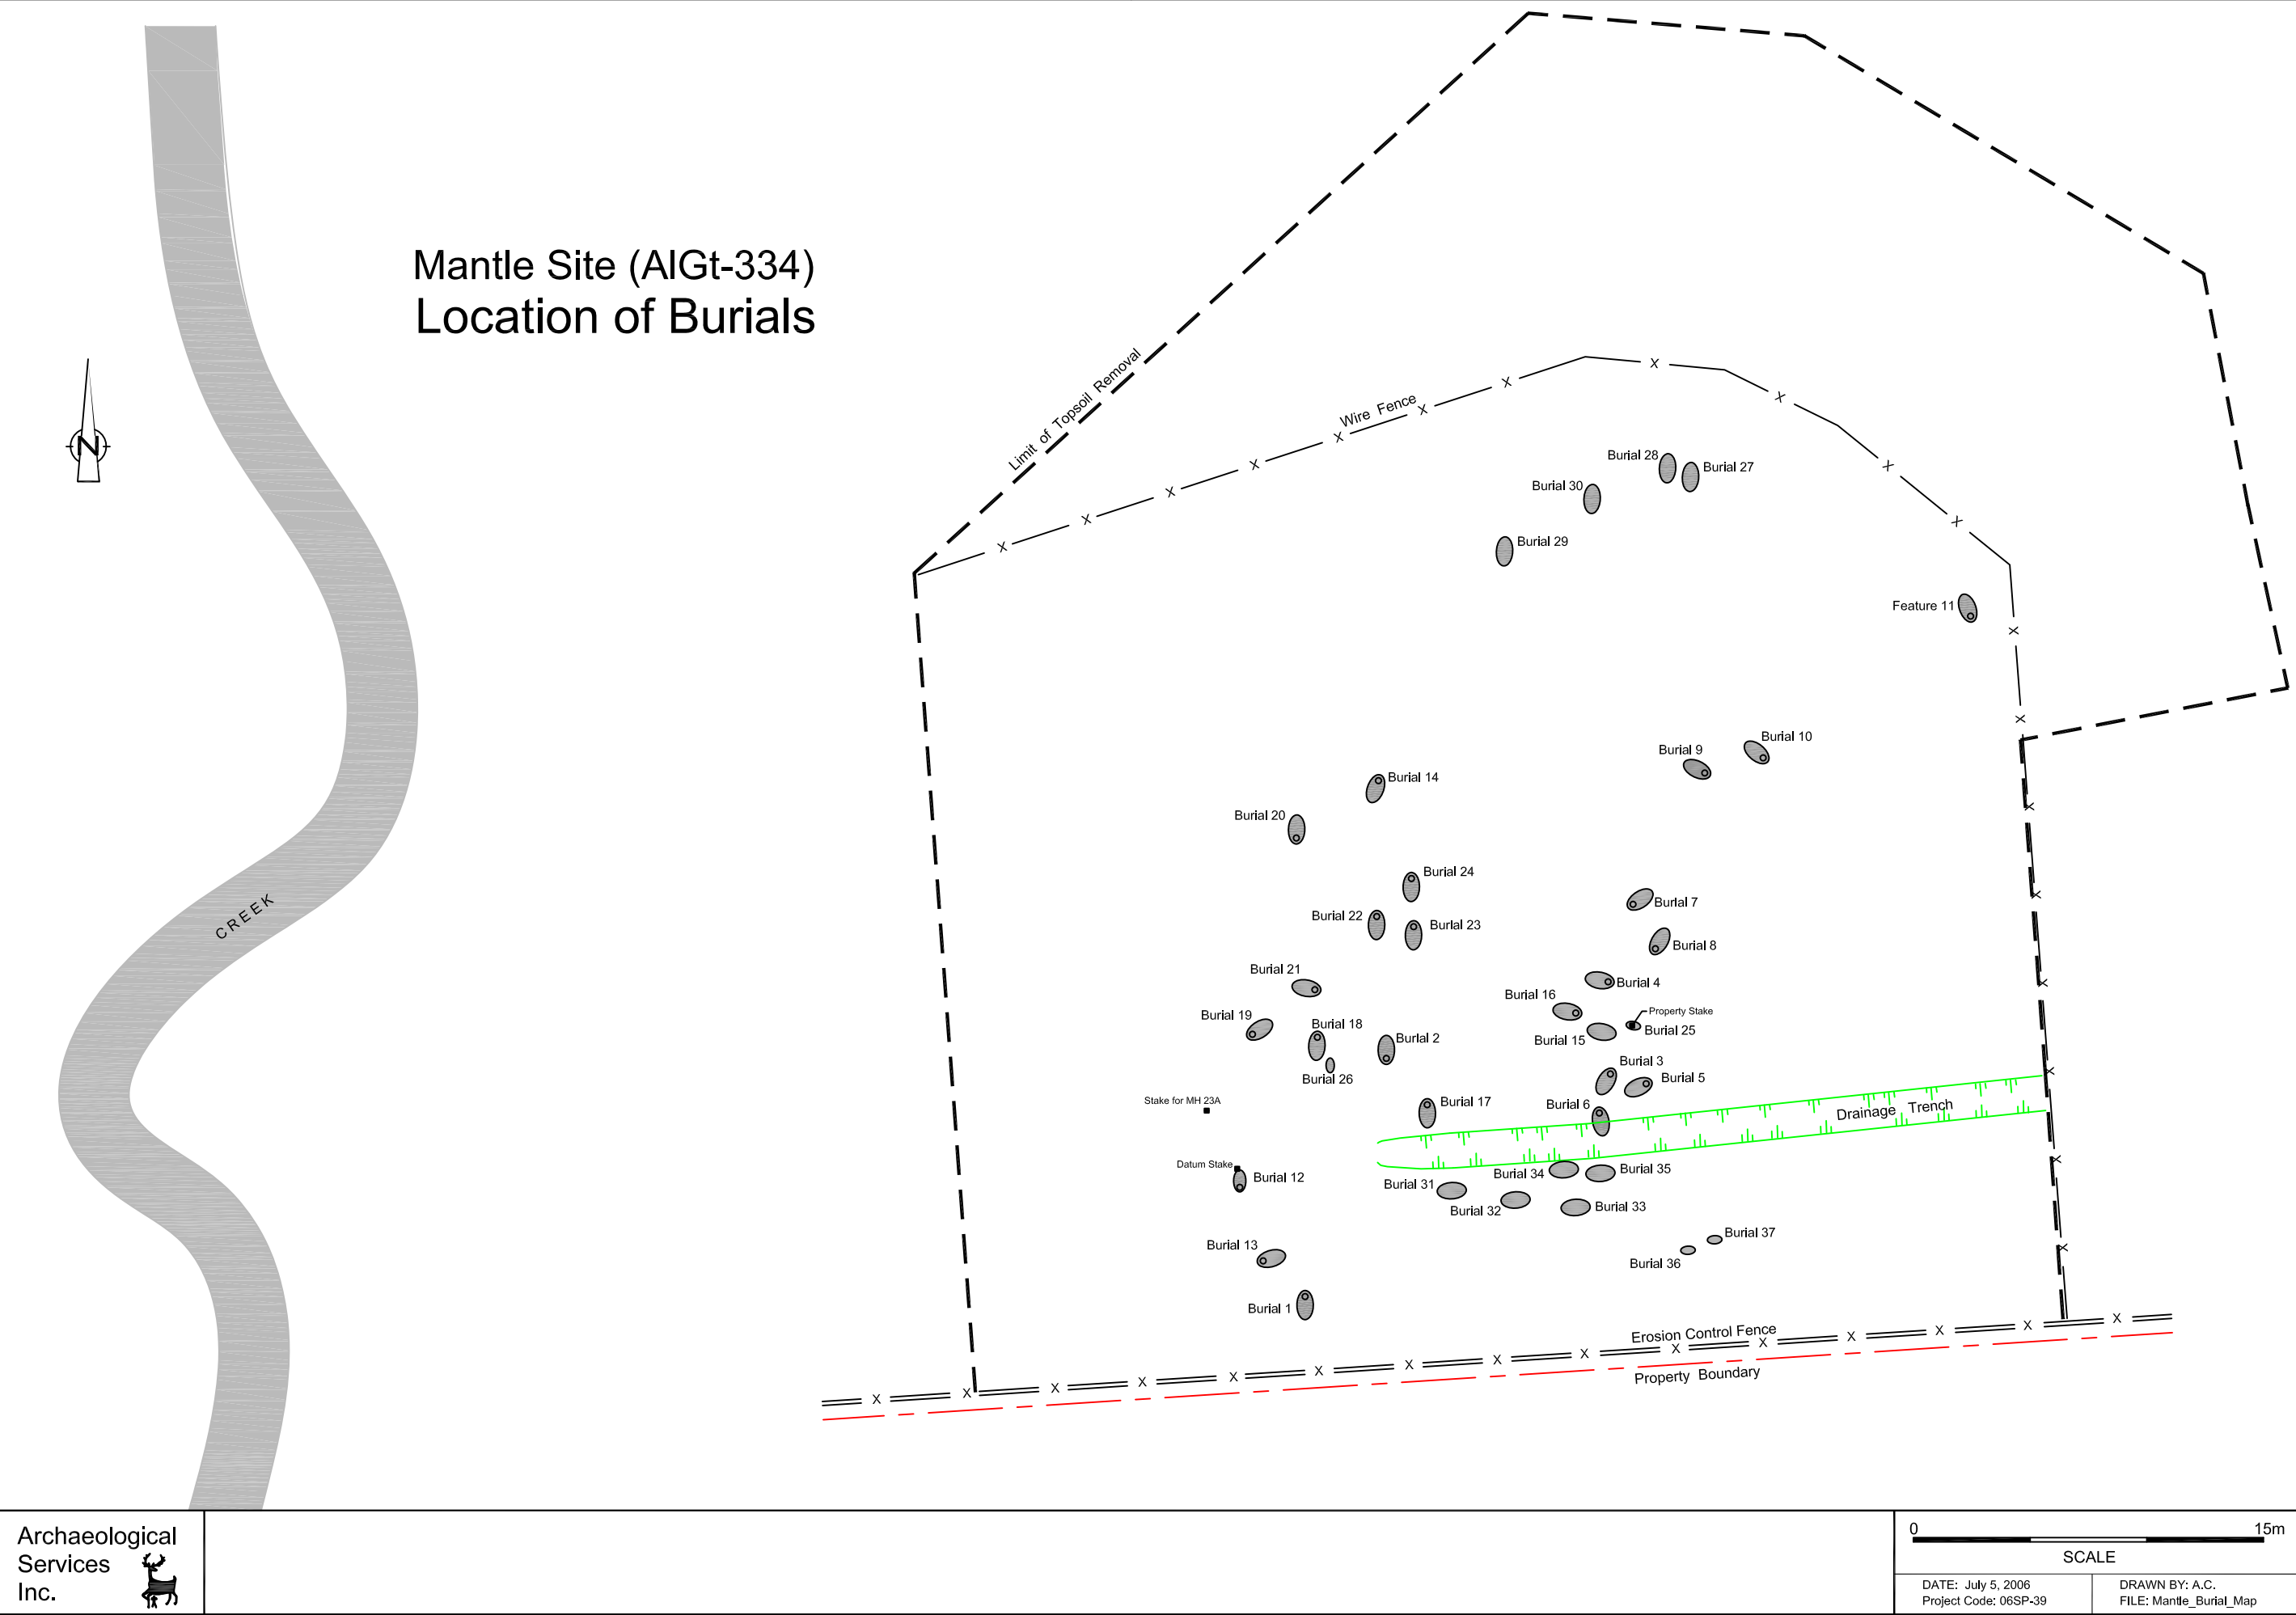

Figure 4: Mantle Cemetery

At least three of the burials had associated artifacts in the form of shell and bone beads, and Burial 7 also had red ochre to the east of both crania. Plates 6,7,and 8 not only show the variation of the population buried within the Mantle cemetery, but also the variation in the ways in which they were interred.

It is clear that Burial 6 and Burial 34 were partially disturbed by the trenching of the drainage ditch and Burials 1 and 2 were also partially impacted by the grading of the bulldozer. Feature 11, isolated in the northeast corner of the site, either represents a severely disturbed burial or redeposition of a series of bones moved from their original context, likely occurring in the nineteenth century. As previously mentioned, this area has been heavily disturbed in the past by farming operations.

It is suggested that together, these burials represent either a portion of the Mantle site primary cemetery where people were buried prior to them being moved at the end of the tenure of the village to the village ossuary, or a cemetery of those who were not intended for ossuary reburial. It is not clear why these people were not included in the ossuary but it may relate to the ways in which they died or to their ethnic identity.

#### 4.0 CONCLUSIONS

Encounters with unmarked Aboriginal burials present unique legal and ethical questions. While some of these questions can only be resolved through an understanding and appreciation of the cultural contexts in which aboriginal peoples lived, died, and were buried, they must also be addressed in the context of current legislation, in this case, the Cemeteries Act (Revised).

While it is likely that the descendents of many of the Late Woodland populations of the Stouffville area ultimately participated in the completion of the formation of the Huron (and Petun) confederacies in the late sixteenth century, their identity prior to that point, that is the identity or identities that they would have ascribed to themselves and their neighbours remains entirely unknown. It is also evident that there are many pitfalls in assuming that the Early, Middle or even Late Ontario “Iroquoian” groups that occupied the region constitute populations *exclusively* ancestral to the historically documented Huron.

This state of affairs has numerous implications for any First Nations consultation process with respect to the treatment of the remains from the Mantle site burial ground, which must take place in accordance with the terms of the Cemeteries Act. In cases involving remains of Aboriginal origin, past precedent has often seen the First Nation that is geographically closest to a burial notified to negotiate a disposition agreement. However, the complex histories of the First Nations of southern Ontario, both before and after European contact and settlement, means that there should be further effort to identify the group or groups that are the most appropriate (on cultural-historical grounds) to represent the descendents of the deceased.

Based on the fact that the Mantle burial ground and village site, like other Ontario Iroquoian communities, was clearly primarily an ancestral Huron community, the Wendat (Hurons of Wendake/Lorette) were included in decisions affecting these remains. However, the Mantle site was also definitely inhabited by people of Oneida (Hauenasane) and Anishnaubeg ancestry. Therefore, the Mississauga of Scugog Island First Nation, who constituted the nearest group, also legitimately expressed interest in the disposition of the remains, as did the Six Nations of the Grand. All these groups participated in the consultation process to reach a disposition agreement.

Regarding the considerations outlined in the Cemeteries Act (Revised) and identified in the introduction to this report, the following conclusions can be made:

1. Based on the data cited above, the remains from the subject area appear to represent a primary burial ground of the Mantle site (AlGt-334) where people were buried prior to being moved at the end of the tenure of the village to the village ossuary, or where they were intended to remain forever.
2. Feature 11 represents a small isolated secondary deposit of bone likely resulting from a severely disturbed burial. These remains were treated like the other disturbed remains and reburied with the bones recovered from the backdirt.
3. As per the written request of First Nations, one tooth per burial was retained for DNA and isotopic testing and each burial was inventoried, recording any possible information about the individual(s). As this cemetery is somewhat unique in the archaeological history of the north shore of Lake Ontario, the ethnicity of the individuals or the reasons for their death could shed significant light on why these people were buried here and how they might relate to the village.
4. The remaining unscreened backdirt was returned to the disturbed excavation trench and the balance was used to cover the burial area. The entire cemetery was then capped with a layer of clean topsoil 20 cm thick, and registered on title to protect it in perpetuity. Other cemetery markings were placed as outlined in the disposition agreement.
5. The Cemeteries Registrar and Fieldgate Developments were encouraged to continue consultation with First Nation representatives (the Hurons of Wendake, the Mississauga of Scugog First Nation in their role as nearest aboriginal group and as representatives of the various Anishnaubeg communities of the north shore of Lake Ontario, and Six Nations of the Grand) in order to reach a formal disposition agreement.

**Notwithstanding** the results and recommendations presented in this study, Archaeological Services Inc. notes that no archaeological assessment, no matter how thorough or carefully completed, can necessarily predict, account for, or identify every form of isolated or deeply buried archaeological deposit. In the event that archaeological remains are found during subsequent construction activities, the consultant archaeologist, approval authority, and the Cultural Programs Unit of the Ministry of Tourism Culture should be immediately notified.

In addition, the following advice on compliance is provided:

- This report is submitted to the Minister of Tourism and Culture as a condition of licensing in accordance with Part VI of the Ontario Heritage Act, RSO 1990, c 0.18. The report is reviewed to ensure that it complies with the standards and guidelines that are issued by the Minister, and that the archaeological field work and report recommendations ensure the conservation, preservation and protection of the cultural heritage of Ontario. When all matters relating to archaeological sites within the project area of a development proposal have been addressed to the satisfaction of the Ministry of Tourism and Culture, a letter will be issued by the ministry stating that there are no

further concerns with regard to alterations to archaeological sites by the proposed development.

- It is an offence under Sections 48 and 69 of the Ontario Heritage Act for any party other than a licensed archaeologist to make any alteration to a known archaeological site or to remove any artifact or other physical evidence of past human use or activity from the site, until such time as a licensed archaeologist has completed archaeological field work on the site, submitted a report to the Minister stating that the site has no further cultural heritage value or interest, and the report has been filed in the Ontario Public Register of Archaeology Reports referred to in Section 65.1 of the Ontario Heritage Act.
- Should previously undocumented archaeological resources be discovered, they may be a new archaeological site and therefore subject to Section 48 (1) of the Ontario Heritage Act. The proponent or person discovering the archaeological resources must cease alteration of the site immediately and engage a licensed consultant archaeologist to carry out archaeological fieldwork, in compliance with sec. 48 (1) of the Ontario Heritage Act.
- The Cemeteries Act, R.S.O 1990 c. C.4 and the Funeral, Burial and Cremation Services Act, 2002, S.O. 2002. c.33 (when proclaimed in force) require that any person discovering human remains must immediately notify the police or coroner and the Registrar of Cemeteries, Ministry of Consumer Services.
- The documentation related to this archaeological assessment will be curated by Archaeological Services Inc. until such a time that arrangements for their ultimate transfer to Her Majesty the Queen in right of Ontario, or other public institution, can be made to the satisfaction of the project owner(s), the Ontario Ministry of Tourism and Culture, and any other legitimate interest groups.
